A SURVEY OF GENERALIZED MATRIX INVERSES

GERHARD ZIELKE

Sektion Mathematik, Martin-Luther-Universität, Halle-Wittenberg, Weinbergweg 17, DDR-402 Halle/Saale, DDR

0. Introduction

Solve:

\[ Ax = b, \]

\( A \in C^{m \times n} \) a given complex \( m \times n \) matrix, \( b \in C^m \) a given vector, \( x \in C^n \) solution vector.

Familiar cases:

- \( A \) square and nonsingular \( \square \):
  \[ x = A^{-1}b \] unique solution.

- \( A \) rectangular and column regular \( \square \) (in general, an overdetermined (linear independent columns) system of equations)
  \[ x = (A^*A)^{-1}A^*b \] unique least-squares solution

\( (A^* = A^T \) the conjugate transpose or adjoint of \( A \).

Method of least squares: \( Ax - b = r \neq 0 \) (residue)

\[ \sum_{i=1}^{m} |r_i|^2 = r^*r = \|Ax - b\|^2 \rightarrow \min ! \text{ (\( \| \cdot \| \) means the Euclidean vector norm).} \]

Investigate the cases:

- \( A \) rectangular and row regular \( \square \) (underdetermined system) (linear independent rows)
- \( A \) square and singular
- \( A \) rectangular and rank deficient

\[ \begin{cases} \text{rank}(A) = r(A) < \min(m, n). \end{cases} \]

QUESTION: Are analogous representations of the solutions \( x = Mb \) or \( x = Mb^+Py, y \) arbitrary, possible? \( M, P \)
Answer: \( M \) generalized inverse, \( P \) projector (representable by a generalized inverse).

1. Penrose definition (derivation)

Wanted: "generalized inverse" \( A^+ \) which satisfies 3 requirements:

1. \( A^+ \) solves a consistent linear system of equations \( Ax = b \) by \( x = A^+ b \),

2. \( A^+ \) yields an approximate solution of an inconsistent linear system of equations in the least squares sense by \( x = A^+ b \),

3. \((A^+)^+ = A\), analogous to \((A^{-1})^{-1} = A\).

1.1. \( Ax = b \) consistent (has a solution), i.e., \( b \in R(A) = \{y \in C^n | Ax = y, x \in C^n \} \) column space of \( A \) or range of \( A \). \( x = A^+ b \) shall be solution of \( Ax = b \Rightarrow AA^+ b = b \) (condition of consistency). Since \( b \in R(A) \), and hence \( b = Ax, x \in C^n \), it follows \( AA^+ Ax = Ax, z \) arbitrary (depends only on \( b \))

\[ \Rightarrow AA^+ A = A. \]

1.2. \( Ax = b \) inconsistent (has no solution)

\( x = A^+ b \) shall be solution of \( \|Ax - b\| = \text{min} \), i.e.,

\[ \|AA^+ b - b\| \leq \|Ax - b\| \quad \forall x \in C^n, b \in C^m. \]

By rewriting \( Ax - b = AA^+ b - b + A(x - A^+ b) \) we obtain

\[ \|AA^+ b - b\| \leq \|AA^+ b - b + Ay\| \quad \forall b \text{ and } y = x - A^+ b, \]

and by using the abbreviations \( u = AA^+ b - b \) and \( v = Ay \) it follows

\[ \|u\| \leq \|u + v\| \]

or because of \( \|u\|^2 = u^* u \)

\[ u^* u \leq (u + v)^* (u + v) = u^* u + v^* v + u^* v + v^* u. \]

Because of \( v^* u = u^* v \) we obtain the inequality

\[ 0 \leq v^* v + 2 \Re (u^* v). \]

Since \( v^* v = \|v\|^2 \geq 0 \) and \( u^* v = (AA^+ b - b)^* Ay = b^* (A^+ A A^* A - A) y \) depends on arbitrary vectors \( b \) and \( y \), this inequality is equivalent to the requirement \( u^* v = 0 \) or

\[ A^+ A^* A = A. \]

However, this requirement and the two equations

\[ AA^+ A = A, \]

\[ (AA^+)^* = AA^+ \]
are equivalent. For by substituting the second in the first equation we obtain \( A^{+}A^{*}A = A \). Conversely, from this follows by multiplying on the right by \( A^{+} \) that

\[
AA^{+} = A^{+}A^{*}AA^{+} = (AA^{+})^{*}AA^{+}
\]

is Hermitian and hence

\[
A = A^{+}A^{*}A = (AA^{+})^{*}A = AA^{+}A.
\]

1.3. Equivalence to the Penrose equations.

**Theorem 1.** The requirements for \( A^{+} \) and the four equations \((P1), \ldots, (P4)\) are equivalent:

\[
\begin{align*}
AA^{+}A &= A & (F1) \\
(AA^{+})^{*} &= AA^{+} & (F2) \\
(A^{+})^{*} &= A & (F3) \\
(AA^{+})^{*} &= AA^{+} & (F4)
\end{align*}
\]

\[
\begin{align*}
AA^{+}A &= A & (P1) \\
A^{+}AA^{+} &= A^{+} & (P2) \\
(AA^{+})^{*} &= AA^{+} & (P3) \\
(A^{+}A)^{*} &= A^{+}A & (P4)
\end{align*}
\]

*Proof.* If we replace \( A \) by \( A^{+} \) in \((F1)\) and \((F2)\) and consider \((F3)\) we obtain the equations \((P2)\) and \((P4)\). Conversely, the equations \((P1), \ldots, (P4)\) are symmetric in \( A \) and \( A^{+} \); that means they define \( A^{+} \) as the generalized inverse of \( A \) and \( A \) as the generalized inverse of \( A^{+} \), but that means \( A = (A^{+})^{+} \).

**Definition 1** (Penrose [35]). The \( n \times m \) matrix \( A^{+} \) is called **Moore-Penrose inverse of the \( m \times n \) matrix** \( A \) if \( A^{+} \) satisfies the four conditions

\[
\begin{align*}
AA^{+}A &= A & (P1) \\
A^{+}AA^{+} &= A^{+} & (P2) \\
(AA^{+})^{*} &= AA^{+} & (P3) \\
(A^{+}A)^{*} &= A^{+}A & (P4)
\end{align*}
\]

(Penrose equations).

**Remarks.** 1. In the original definition of Penrose \( A^{+} \) is called "generalized inverse".

2. Every matrix \( A \) has a unique matrix \( A^{+} \) (Penrose [35]).

2. Other equivalent definitions of the Moore-Penrose inverse

**Definition 2.** \( A^{+} \) is called **Moore-Penrose inverse of** \( A \) if \( A^{+}b \) is the least-squares solution of \( Ax = b \) with minimal Euclidean norm.

**Theorem 2.** The Definitions 1 and 2 are equivalent.

*Proof.* According to 1.2 \( x = Gb \) is a solution of the minimum problem \( \|Ax - b\| = \text{min} \) if and only if \( AGA = A \) \((P1)\) and \( (AG)^{*} = AG \) \((P3)\).
The *general* least-squares solution is

\[(*) \quad x = Gb + (I - GA)z, \quad z \text{ arbitrary}, \]

\(x\) is a least-squares solution because \(A(I - GA)z = 0\); every least-squares solution \(G, b\) can be represented in the form (\(*\)) by choosing \(z = G, b - Gb;\) cf. 6.5). According to Definition 2 \(G = A^+\) must satisfy the inequality

\[
\|Gb\| \leq \|Gb + (I - GA)z\| \quad \forall b, z.
\]

By using the abbreviations \(u = Gb\) and \(v = (I - GA)z\) this inequality, analogous to Section 1.2, leads to the requirement

\[u^*v = b^*G^*(I - GA)z = b^*(G^* - G^*GA)z = 0, \quad \forall b, z,\]

hence \(G^* = G^*GA\). But it holds the equivalence

\[
G^* = G^*GA \quad \text{(or } G = A^*G^*G) \Leftrightarrow \begin{cases} 
GAG = G \quad \text{(P2)} \\
(GA)^* = GA \quad \text{(P4)},
\end{cases}
\]

for by substituting (P4) in (P2) we obtain \(A^*G^*G = G\), and conversely, from this it follows by multiplying on the right by \(A\) that \(GA = A^*G^*GA = (GA)^*GA\) is Hermitian and thus we have \(G = A^*G^*G = (GA)^*G = GAG\).

Thus \(G = A^+\).

**Definition 3** (Moore [29]). \(A^+\) is called *Moore–Penrose inverse of \(A\)* if

1. \(AA^+A = A\),
2. the rows of \(A^+\) are linear combinations of the rows of \(A^*\),
3. the columns of \(A^+\) are linear combinations of the columns of \(A^*\).

**Remark.** (2) means \(A^+ = YA^*\) and (3) means \(A^+ = A^*Z\) for suitable \(Y\) and \(Z\).

**Definition 4** (Ben-Israel, Charnes [4]). \(A^+\) is called *Moore–Penrose inverse of \(A\)* if

1. \(AA^+ = P_{R(A)}\), \(P_{R(A^+)}\): orthogonal projector on \(R(A)\),
2. \(A^+A = P_{R(A)}\), \(P_{R(A^+)}\): orthogonal projector on \(R(A^+)\).

**Remark.** \(P_{R(A)}\) can be defined by the following properties:

- \(P_{R(A)}^* = P_{R(A)}\) (Hermitian), \(P_{R(A)}A = A\), \(r(P_{R(A)}) = r(A)\).

3. Some properties of the Moore–Penrose inverse

1. \((A^+)^+ = A\) (from Theorem 1);
2. \((A^*)^+ = (A^+)^*\); short: \(A^{**} = A^{+*}\);
3. \((AA^*)^+ = A^{+*}A^+, (A^*A)^+ = A^+A^{+*}\);
(4) $A^+ = (A^*A)^+A^* = A^*(AA^*)^+$
$= A^+A^*A^* = A^*A^+A^+$ (cf. Def. 3);
   (P2) & (P3) & (P2) & (P4)

(5) $A^* = A^*AA^+ = A^+AA^*$
   (P1) & (P3) & (P1) & (P4)

(6) $(AA^+)^+ = AA^+$, $(A^+A)^+ = A^+A$;

(7) The matrices $AA^+ = P_{R(A)}$, $A^+A = P_{R(A^*)}$, $I - AA^+ = P_{N(A^*)}$,
     $I - A^+A = P_{N(A)}$ are Hermitian and idempotent (orthogonal projectors);

(8) $A^*, AA^*, A^*A, A^+, AA^+ + A^+A$ have the same rank like $A$,
     moreover $r(A) = \text{trace}(AA^+) = \text{trace}(A^+A)$.

4. Moore–Penrose inverses of some special matrices

(1) $A$ nonsingular: $A^+ = A^{-1}$ ordinary inverse;

(2) $A \in \mathbb{C}^{m \times n}$ of full rank:
   column regular $\square$, $r(A) = n$:

   $A^+ = A^{-1} = (A^*A)^{-1}A^*$ left inverse, $A^+A = I_n$;
   $A$ row regular $\square$, $r(A) = m$:

   $A^+ = A^{-1}_R = A^*(AA^*)^{-1}$ right inverse, $AA^+ = I_m$;

(3) Zero matrix: $0^+ = 0^T$;

(4) Scalar $a$: $a^+ = \begin{cases} 1/a & \text{if } a \neq 0, \\ 0 & \text{if } a = 0 \end{cases}$;

(5) Diagonal matrix:

   $D = \text{diag}(d_1, d_2, \ldots, d_n)$, $D^+ = \text{diag}(d_1^+, d_2^+, \ldots, d_n^+)$;

(6) $(a \cdot A)^+ = (1/a)A^+$ ($a \neq 0$ scalar), especially $(-A)^+ = -A^+$;

(7) $A$ Hermitian ($A = A^*$), then $A^+$ Hermitian and $AA^+ = A^+A$;

(8) $A$ Hermitian and idempotent ($A = A^*$, $A^2 = A$, i.e., $A$ orthogonal projector), then $A^+ = A$;

(9) $v$ column vector ($\neq 0$), then $v^+ = \frac{v^*}{v^*v} = \frac{v^*}{\|v\|^2}$;

$v^*$ row vector ($\neq 0$), then $v^{*+} = \frac{v}{v^*v} = \frac{v}{\|v\|^2}$;
\[(10) \ A = uv^* \ (i.e. \ r(A) = 1), \ \text{then} \]
\[A^+ = \frac{A^*}{(u^*u)(v^*v)} = \frac{A^*}{\|u\|^2\|v\|^2} = \frac{A^*}{\text{trace}(A^*A)} \ 	ext{(this is true for every matrix of rank 1)};\]

\[(11) \ A \ m \times n \text{ matrix with } a_{ij} = 1 \ \forall i, j, \ \text{then} \ A^+ = \frac{1}{m \cdot n} A^T;\]

\[(12) \ A = \begin{bmatrix} B \\ C \end{bmatrix} \ \text{and} \ BC^* = 0, \ \text{then} \ A^+ = (B^+, C^+), \ \text{especially:} \begin{bmatrix} B^+ \\ 0 \end{bmatrix} = (B^+, 0);\]

\[(13) \ A = (B, C) \ \text{with} \ B^*C = 0, \ \text{then} \ A^+ = \begin{bmatrix} B^+ \\ C^+ \end{bmatrix}, \ \text{especially:} \ (B, 0)^+ = \begin{bmatrix} B^+ \\ 0 \end{bmatrix};\]

\[(14) \ A = \begin{bmatrix} B & 0 \\ 0 & C \end{bmatrix}, \ \text{then} \ A^+ = \begin{bmatrix} B^+ & 0 \\ 0 & C^+ \end{bmatrix};\]

\[(15) \ A = BC, \ B \ \text{column regular}, \ C \ \text{row regular}, \ \text{then} \]
\[A^+ = C^+B^+ = C^*(CC^*)^{-1}(B^*B)^{-1}B^* \ 	ext{(the reverse order law is not true in general)};\]

\[(16) \ A = UBV^*, \ \text{where} \ U, V \ \text{have orthonormal columns (especially} \ U, V \ \text{unitary matrices), then} \]
\[A^+ = VB^+U^*.\]

5. Classification of generalized inverses

In addition to the unique solution \(X = A^+\) of the four Penrose equations
\[
AXA = A \quad (P1) \quad (AX)^* = AX \quad (P3) \\
XAX = X \quad (P2) \quad (XA)^* = XA \quad (P4)
\]
also matrices \(X\) are of interest which satisfy only part of these equations, but at least (P1). In general, they are no longer determined uniquely. We obtain 8 classes of generalized inverses, e.g. the class of all \(A^{1,4}\) or (1, 4)-inverses:
\[\{A^{1,4}\} = \{X \mid AXA = A, (XA)^* =XA\}.\]

For the (1)-inverse instead of \(A^1\) we use the symbol \(A^-\) introduced by Rao [39].
### Classification

<table>

Inclusions: $\{A^+\} \subseteq \{A^{1,2,3}\} \subseteq \{A^{1,3}\} \subseteq \{A^-\}$ etc.
Intersection of classes, e.g. $\{A^+\} = \{A^{1,4}\} \cap \{A^{1,2,3}\}$.

### 6. Applications of generalized inverses to the solution of linear systems of equations (Zielke [53])

#### 6.1. Condition of consistency (solvability of $Ax = b$).

3 equivalent conditions:

1. $r(A) = r(A, b)$ ($r(A) = \dim R(A) = r$),
2. $b \in R(A)$,
3. $AA^+b = b$ (see also 1.1).

**Proof.** $r(A) = r(A, b) \Rightarrow R(A) = R(A, b) = b \in R(A) \Rightarrow b = Ax$
$\Rightarrow AA^+b = AA^+Ax = Ax = b \Rightarrow (A, b) = (A, AA^+b) \Rightarrow R(A, b)$
$= R(A(I, A^+b)) \subseteq R(A)$, since $R(A) \subseteq R(A, b)$ it holds even the equality
$R(A, b) = R(A) \Rightarrow r(A, b) = r(A)$.

#### 6.2. Solution of the homogeneous system $Ax = 0$ (always solvable).

For any matrix $A \in C^{m \times n}$ we denote by $N(A) = \{x \in C^n \mid Ax = 0\}$ the null space of $A$. It holds $N(A) = R(A^*)^\perp$, i.e. $N(A)$ is the orthogonal complement of $R(A^*)$ and conversely; for if $A^*y = z$ and $Ax = 0$ then $x^*x = y^*Ax = 0 \Leftrightarrow z \perp x$, i.e. all $z \in R(A^*)$ and $x \in N(A)$ are orthogonal to each other.

**General solution of** $Ax = 0$:

$$ x_h \in N(A) = R(A^*)^\perp,$$

(*) \quad $x_h = B_{N(A)}y$, \quad $y \in C^{n-r}$ arbitrary, $B_{N(A)}$ basis of $N(A)$.

For the representation of $x_h$ by means of generalized inverses we consider $I_n - A^+A$. We show that $R(I_n - A^+A) = R(B_{N(A)}) = N(A)$. Firstly, $A(I_n - A^+A) = 0 \Rightarrow R(I_n - A^+A) \subseteq N(A)$. Secondly, from $Ax = 0 \Rightarrow A^+Ax = 0$, i.e. $x - A^+Ax = x$ or $(I_n - A^+A)x = x \Rightarrow x \in R(I_n - A^+A)$
\( \forall x \in N(A) \Rightarrow N(A) \subseteq R(I_n - A^\perp A) \). Thus in (*) \( B_{N(A)} \) can be replaced by \( I_n - A^\perp A \), and we obtain the general solution of the homogeneous system

\[ x_h = (I_n - A^\perp A)y, \quad y \in C^n \text{ arbitrary}, \quad A^\perp \text{ arbitrary } (1)\text{-inverse of } A. \]

**Remark.** \( I_n - A^\perp A \) is a (in general, nonorthogonal or oblique) projector from \( C^n \) on \( N(A) \).

### 6.3. Solution of the consistent inhomogeneous system \( Ax = b \)

**General solution**

\[ x = x_1 + x_h, \]

\( x_1 = x_1(b) \) special solution, e.g. \( x_1 = A^\perp b \) (which follows from the condition of consistency \( AA^\perp b = b \)) or

\[ x = A^\perp b + (I_n - A^\perp A)y, \quad y \in C^n \text{ arbitrary}. \]

**Special case:** underdetermined row regular system: \( \begin{array}{c} n \\ m \end{array} \)

\( r(A) = m < n \), always solvable, because a right inverse exists and (since \( AA_R^{-1} = I \)) therefore \( AA_R^{-1}b = b \) is true.

**General solution:**

\[ x = A_R^{-1}b + (I_n - A_R^{-1}A)y, \quad y \in C^n \text{ arbitrary}. \]

**Special right inverse:** \( A_R^{-1} = A^* (AA^*)^{-1}. \)

### 6.4. Minimum norm solution (normal solution)

Unique solution of the inhomogeneous system with minimal Euclidean norm: \( \|x\| = \min_{Ax=b} \)

We choose the particular solution

\[ \bar{x} \in N(A)^\perp = R(A^*), \]

then

\[ \|x\|^2 = \|\bar{x}\|^2 + \|x_h\|^2 \geq \|\bar{x}\|^2, \]

that is, \( \bar{x} \) is the solution of minimum norm. One obtains \( \bar{x} \) by orthogonal projecting any particular solution onto \( R(A^*) \):

\[ \bar{x} = x_{\text{min}} = P_{R(A^*)}x_1. \]

Since \( P_{R(A^*)} = A^+A = A^{1,4}A \) and \( A^{1,4}A x_1 = A^{1,4}b \), we get the result

\[ x_{\text{min}} = A^{1,4}b, \quad A^{1,4} \text{ arbitrary } (1,4)\text{-inverse of } A. \]

### 6.5. Least-squares solution.

**Theorem 3.** The following conditions characterizing \( x \) as least-squares solution of the inconsistent system \( Ax = b \) are equivalent.

(1) \( \|Ax - b\| = \min_{x \in C^n} \),
A survey of generalized matrix inverses

\(2\) \(Ax = P_{R(A)}b\),
\(3\) \(A^*Ax = A^*b\) (Gaussian transformation) \{consistent.\}

Proof. \((1) \Leftrightarrow (2):\) Consider the expression

\((\ast)\) \[\|Ax - b\|^2 = \|(Ax - P_{R(A)}b) - (I - P_{R(A)})b\|^2.\]

Obviously,

\((Ax - P_{R(A)}b) \in R(A)\) and \((I - P_{R(A)})b \in R(A)'^\perp\)

because of \(b^*(I - P_{R(A)})^*Ax = b^*(I - P_{R(A)})Az = 0.\) Using the generalized
Pythagorean proposition \((\ast)\) can be written in the form

\[\|Ax - b\|^2 = \|Ax - P_{R(A)}b\|^2 + \|(I - P_{R(A)})b\|^2.\]

Obviously, this expression takes its smallest value if and only if
\(Ax = P_{R(A)}b\).

\((2) \Leftrightarrow (3):\) From \((2)\) it follows with \((P1), (P3)\) and \(A^{+\ast} = A^{\ast\ast}\) by
multiplying on the left by \(A^*\)

\[A^{\ast\ast}Ax = A^*P_{R(A)}b = A^*AA^+b = A^*A^{\ast\ast}A^*b = A^*b,\]

i.e. \((3)\).

Conversely, multiplying \((3)\) on the left by \(A^{+\ast}\) gives

\[A^{+\ast}A^*Ax = A^{+\ast}A^*b\]

or with \((P3)\)

\[AA^+Ax = Ax = AA^+b = P_{R(A)}b,\]

i.e. \((2)\).

The general least-squares solution is obtained, for instance, by solving
the consistent system \(Ax = P_{R(A)}b\), namely

\[x = A^{-}P_{R(A)}b + x_h\]

or

\[x = A^{13}b + (I_n - A^{-}A)y,\]

\(y \in C^n\) arbitrary, and \(A^{13}\) arbitrary \((1, 3)\)-inverse of \(A\), because \(A^{-}P_{R(A)} = A^{-}AA^+ = A^{13}\), for \(A^{-}AA^+\) satisfies \((P1)\) and \((P3)\).

Special case: overdetermined column regular system: \(\Box^m_n\)
\(r(A) = n < m\). From \((3)\) follows the unique solution

\[x = (A^*A)^{-1}A^*b.\]

\((A^*A)^{-1}A^* = A^{-1}_{\perp}A_{\perp}^{-1}\) is a special left inverse of \(A\), because of \(A^{-1}_{\perp}A = I.\)

6.6. Best approximate solution (minimal least-squares solution, pseudo
normal solution). Unique least-squares solution of minimum Euclidean
norm, that is, the solution of the minimum problem

\[ \|x\| = \min_{x \in \mathcal{X}} \text{ with } \mathcal{X} = \{ x \mid \|Ax - b\| = \min \} \]

Similarly to the minimum norm solution we obtain the best approximate solution by orthogonal projecting a least-squares solution on \( \mathcal{R}(A^*) \):

\[ x_{\text{best}} = P_{\mathcal{R}(A^*)}[A^{1,3}b + (I_n - A^+A)y] \]

\[ = A^+A^{1,3}b = A^+A(A^-AA^+)b = A^+AA^+b, \]

hence

\[ x_{\text{best}} = A^+b. \]

In principle: all cases can be covered by

\[ x = A^+b - (I_n - A^+A)y, \quad y \in \mathbb{C}^n \text{ arbitrary.} \]

\( y = 0 \) gives the \( x \) of smallest norm. But in general the computational amount will be smaller if instead of \( A^+ \) the appropriate generalized inverses \( A^- \), \( A^{1,3} \) or \( A^{1,4} \) are used.

7. Computation of generalized inverses and numerical solution of linear equations by transforming into normal form

Procedure. Transforming the given matrix into a simpler form and representing the generalized inverses by means of the transformation matrices.

**Theorem 4.** Let the matrix \( A \in \mathbb{C}^{m \times n} \) of rank \( r < \min(m, n) \) be transformed into the normal form

\[ PAQ = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} \]

by the nonsingular matrices \( P = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} \) and \( Q = (Q_1, Q_2) \), where \( P_1 \) indicates the first \( r \) rows of \( P \) and \( Q_1 \) the first \( r \) columns of \( Q \). Then, the generalized inverses of \( A \) have the following general representations in which \( X, Y \) and \( Z \) are arbitrary matrices of suitable size.

\[
\begin{align*}
(1) \quad A^- &= Q \begin{bmatrix} I_r & X \\ Y & Z \end{bmatrix} P \quad \text{(Rohde [42])}, \\
(2) \quad A^{1,3} &= Q \begin{bmatrix} I_r & X \\ Y & YY \end{bmatrix} P \quad \text{(Rohde [42])}
\end{align*}
\]

\[ = Q \begin{bmatrix} I_r \\ Y \end{bmatrix} (I_r, X)P, \]
\( A^{1,3} = Q \begin{bmatrix} I_r & -P_1P_2^+ \end{bmatrix} P, \)

\( A^{1,4} = Q \begin{bmatrix} I_r & -Q_1 \end{bmatrix} P, \)

\( A^{1,2,3} = Q \begin{bmatrix} I_r & -P_1P_2^+ \end{bmatrix} P \quad \text{(Morris, Odell [31])} \)

\[ = Q \begin{bmatrix} I_r \\ Y \end{bmatrix} (I_r, -P_1P_2^+)P, \]

\( A^{1,2,4} = Q \begin{bmatrix} I_r & X \\ -Q_1^+Q_1 & -Q_1^+Q_1 \end{bmatrix} P = Q \begin{bmatrix} I_r \end{bmatrix} (I_r, X) P, \)

\( A^{1,3,4} = Q \begin{bmatrix} I_r & -P_1P_2^+ \end{bmatrix} P, \)

\( A^+ = Q \begin{bmatrix} I_r & -P_1P_2^+\end{bmatrix} \begin{bmatrix} P_1^+P_2^+ \\ -Q_1^+Q_1 \end{bmatrix} P \quad \text{(Morris, Odell [31])} \)

\[ = Q \begin{bmatrix} I_r \\ Y \end{bmatrix} (I_r, -P_1P_2^+)P. \]

**Proof** (see Zielke [49], [52]).

**Remarks.**

1. Because of

\[ A^{1,2} = A_1^-A_2^- \quad (A_1^-, A_2^- \text{ arbitrary (1)-inverses}) \]

\[ = Q \begin{bmatrix} I_r & X_1 \\ Y_1 & Z_1 \end{bmatrix} PP^{-1} \begin{bmatrix} I_r \\ 0 \end{bmatrix} (I_r, 0)Q^{-1}Q \begin{bmatrix} I_r & X_2 \\ Y_2 & Z_2 \end{bmatrix} P = Q \begin{bmatrix} I_r \\ Y_1 \end{bmatrix} (I_r, X_2) P \]

the generalized inverses \( A^{1,2}, A^{1,2,3}, A^{1,3,4} \) and \( A^+ \) can be written in this product form with arbitrary or specified \( Y_1, Y_2 \).

2. Since \( P_2 \) and \( Q_2 \) have full rank, it holds

\[ P_2^+ = P_2^*P_2P_2^*^{-1} \quad Q_2^+ = (Q_2^*Q_2)^{-1}Q_2^*. \]

3. If \( A \) is a full-rank matrix, then, in the case

A column regular [] :

\[ A^- = A^{1,2} = A^{1,4} = A^{1,2,4} = Q(I_n, X)P, \quad X \text{ arbitrary}, \]

\[ A^{1,3} = A^{1,2,3} = A^{1,3,4} = A^+ = Q(I_n, -P_1P_2^+)P. \]

A row regular [] :

\[ A^- = A^{1,2} = A^{1,3} = A^{1,2,3} = Q \begin{bmatrix} I_m \\ Y \end{bmatrix} P, \quad Y \text{ arbitrary}, \]

\[ A^{1,4} = A^{1,2,4} = A^{1,3,4} = A^+ = Q \begin{bmatrix} I_m \\ -Q_1^+Q_1 \end{bmatrix} P. \]
4. Also transformations into other normal forms and by other matrices 
(e.g. orthogonal (unitary) matrices) are possible and usual.

**Corollary.** If \( X, Y \) and \( Z \) in Theorem 4 are replaced by zero matrices, 
then we obtain the particular generalized inverses

\[
A_1^{-} = Q \left[ \begin{array}{cc}
I_r & 0 \\
0 & 0
\end{array} \right] P = Q_1 P_1,
\]

\[
A_1^{1.3} = Q \left[ \begin{array}{cc}
I_r & 0 \\
0 & -P_1 P_2^+
\end{array} \right] P = Q_1 P_1 (I_m - P_2^+ P_2),
\]

\[
A_1^{1.4} = Q \left[ \begin{array}{cc}
I_r & 0 \\
0 & -Q_2^+ Q_1
\end{array} \right] P = (I_n - Q_2 Q_2^+) Q_1 P_1.
\]

Moreover, \( A^+ \) can be written in the product form

\[
A^+ = (I_n - Q_2 Q_2^+) Q_1 P_1 (I_m - P_2^+ P_2).
\]

### 7.2. Linear equations

**Theorem 5.** Let \( A \in C^{m \times n} \) of rank \( r \) be transformed into the normal 
form \( PAQ = \left[ \begin{array}{cc}
I_r & 0 \\
0 & 0
\end{array} \right] \) as in Theorem 4. Then, for the solution of linear 
equations \( Ax = b \) we yield the following results:

Condition of consistency (necessary and sufficient for the solvability 
of \( Ax = b \))

\[
P_2 b = 0.
\]

General solution of the homogeneous system \( Ax = 0 \)

\[
x = Q_2 y, \quad y \in C^{n-r} \text{ arbitrary}.
\]

General solution of the consistent inhomogeneous system \( Ax = b \)

\[
x = Q_1 P_2 b + Q_2 y, \quad y \in C^{n-r} \text{ arbitrary}.
\]

Minimum norm solution (solution of the minimum problem \( \|x\| = \min \))

\[
x = (I_n - Q_2 Q_2^+) Q_1 P_1 b.
\]

General least-squares solution (general solution of the minimum problem \( \|Ax - b\| = \min \))

\[
x = Q_1 P_1 (I_m - P_2^+ P_2) b + Q_2 y, \quad y \in C^{n-r} \text{ arbitrary}.
\]

Best approximate solution (solution of the minimum problem

\[
\|x\| = \min_{x \in C^n} \text{ with } K = \{x \mid \|Ax - b\| = \min_{x \in C^n}\}.
\]

\[
x = (I_n - Q_2 Q_2^+) Q_1 P_1 (I_m - P_2^+ P_2) b.
\]
Proof. According to Section 6 and Corollary to Theorem 4.

(1) With $A = P^{-1} \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Q^{-1}$ the condition of consistency $AA^{-1}b = b$ can be written in the form

$$P^{-1} \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Q^{-1}Q \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Pb = P^{-1} \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Pb = b$$

or

$$\begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} b = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} b,$$

that is

$$P_2 b = 0.$$

(2) $(I_n - A^{-1}A)y = \left( I_n - Q \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} PP^{-1} \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Q^{-1} \right) y$

$$= \left( I_n - Q \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Q^{-1} \right) y$$

$$= \left( Q \begin{bmatrix} I_r & 0 \\ 0 & I_{n-r} \end{bmatrix} Q^{-1} - Q \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Q^{-1} \right) y$$

$$= Q \begin{bmatrix} 0 & 0 \\ 0 & I_{n-r} \end{bmatrix} Q^{-1} y, \quad y \in C^n \text{ arbitrary,}$$

$$= (Q_1, Q_2) \begin{bmatrix} 0 \\ I_{n-r} \end{bmatrix} (0, I_{n-r}) \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

with $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = z = Q_{21}^{-1}y, \quad z \in C^n \text{ arbitrary,}$

$$= Q_2 x_2, \quad x_2 \in C^{n-r} \text{ arbitrary}.$$

(3) to (6) are obviously true.

For other transformations into block forms see Zielke [54].

7.3. Numerical example. Solve 3 linear systems $A\omega = b$, where

$$A = \begin{bmatrix} 1 & 0 & 1 \\ -1 & 1 & 0 \\ 1 & -1 & 0 \\ 0 & 1 & 1 + \varepsilon \end{bmatrix}, \quad b^{(0)} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad b^{(1)} = \begin{bmatrix} 1 \\ 1 \\ -1 \\ 2 \end{bmatrix}, \quad b^{(2)} = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}.$$

Transforming into normal form $PAQ = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}$ by elementary row or column operations: interchanging, multiplication by a nonzero scalar,
addition of a multiple of a row (column) to another. Determination of $P$ and $Q$ (not unique) according to the scheme

$$
\begin{align*}
P \begin{bmatrix}
I_m & A
\end{bmatrix} Q & = \\
\begin{bmatrix}
P & I_r & 0 \\
I_m & 0 & 0 \\
& & Q
\end{bmatrix}
\end{align*}
$$

Transformation steps:

0 & 0 & 1
\end{bmatrix}$ | Interchange the 3rd and the 4th row. |
| 8.   | $\begin{bmatrix}
1 & 0 & 0 & 0 & 1 & 0 \\
1 & 1 & 0 & 0 & 0 & 1 \\
0 & 1 & 1 & 0 & 0 & 0 \\
-1 & -1 & 0 & 1 & 0 & 0 \\
1 & 0 & -1 \\
0 & 1 & -1 \\
0 & 0 & 1
\end{bmatrix}$ | If $\varepsilon$ lies within the scope of the rounding errors, set $\varepsilon = 0$. Then the numerical rank is 2. |
8.: If \( \varepsilon \) lies significantly above the rounding error level, then e.g., multiply the 3rd row by \( 1/\varepsilon \) and hence the numerical rank is 3.

**Results.** If \( \varepsilon = 0 \) in the given matrix \( A \), we obtain after the 6th step

\[
P = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ -1 & -1 & 0 & 1 \end{bmatrix}, \quad Q = (Q_1, Q_2) = \begin{bmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix},
\]

thus \( r(A) = 2 \). In this case the following results are obtained.

**Condition of consistency** \( P_2b = 0 \): because of

\[
P_2b(1) = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad P_2b(2) = \begin{bmatrix} 2 \\ -1 \end{bmatrix}
\]

it is satisfied for \( b = b(1) \), but not for \( b = b(2) \).

**Solution of the homogeneous system** \( Ax = 0 \):

\[
\begin{align*}
    x &= Q_2y = \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix} \quad \forall y \in \mathbb{C}^{n-r} \quad \text{(scalar)}.
\end{align*}
\]

**Solution of the inhomogeneous consistent system** \( Ax = b(1) \):

\[
\begin{align*}
    x &= Q_1P_1b(1) + Q_2y = \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix} + \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix} \quad \text{with} \quad y = \begin{bmatrix} 1 - y \\ 2 - y \\ y \end{bmatrix}.
\end{align*}
\]

**Minimum norm solution:**

\[
x = (I_n - Q_2Q_2^+)'Q_1P_1b(1) = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} \quad \text{with} \quad Q_2^+ = \frac{1}{3}(-1, -1, 1).
\]

**Least-squares solution of** \( Ax = b(2) \):

\[
\begin{align*}
    x &= Q_1P_1(I_n - P_2^+P_2)b(2) + Q_2y = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} + \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix} y = \begin{bmatrix} 1 - y \\ 1 - y \\ y \end{bmatrix}.
\end{align*}
\]

with

\[
P_2^+ = \frac{1}{5} \begin{bmatrix} -1 & -2 \\ 2 & -1 \\ 3 & 1 \\ 1 & 2 \end{bmatrix}.
\]
Best approximate solution:

\[ a = (I_n - Q_1^2 Q_2^3) Q_1 P_1 (I_m - P_2^3 P_2^3) b^{(3)} = \frac{1}{3} \begin{bmatrix} 1 \\ 1 \\ 2 \end{bmatrix}. \]

Moreover, we obtain the particular generalized inverse (even (1, 2)-inverse)

\[ A_1^{-} = Q_1 P_1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} A_0^{-} \\ 0 \\ 0 \end{bmatrix}, \]

and the Moore-Penrose inverse

\[ A^+ = \frac{1}{15} \begin{bmatrix} 4 & -3 & 3 & 1 \\ 1 & 3 & -3 & 4 \\ 5 & 0 & 0 & 5 \end{bmatrix}. \]

In the case \( \epsilon \neq 0 \) we obtain, also for \( \epsilon \) with a small absolute value (and just for these values), completely different results. This shows already \( A_1^{-} \) which reads for \( \epsilon \neq 0 \):

\[ A_1^{-} = QP_1 = \begin{bmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ -1 & -1 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 + \frac{1}{\epsilon} & \frac{1}{\epsilon} & 0 & -\frac{1}{\epsilon} \\ \frac{1}{\epsilon} & 1 + \frac{1}{\epsilon} & 0 & -\frac{1}{\epsilon} \\ -\frac{1}{\epsilon} & -\frac{1}{\epsilon} & 0 & \frac{1}{\epsilon} \end{bmatrix}. \]

From this comparison we learn that the elements of generalized inverses do not continuously depend on the elements of the given matrix if the rank changes.

7.4. Minimum rank. In general, an exact determination of the rank of (nearly) rank-deficient matrices is not possible in a finite arithmetic. In order to avoid an incorrect increase of the rank by rounding errors one uses the so-called minimum rank.

Definition 5. \( r_s(A) \) is called minimum rank (or numerical rank, pseudo rank) of the matrix \( A \) with respect to a tolerance \( \epsilon \) and a norm \( \| \cdot \| \), if

\[ r_s(A) = \min_{\| \Delta A \| \|A\| \leq \epsilon} r(A + \Delta A) \]

for a sufficiently large \( \epsilon > 0 \).
A SURVEY OF GENERALIZED MATRIX INVERSES 515

Because a slight increase of $\varepsilon$ can decrease the minimum rank we need an upper bound on $\varepsilon$ so that for such $\varepsilon \gamma_1(A) < \gamma(A)$ does not occur. By using the spectral norm $\|A\|_2 = (\max \text{. eigenvalue of } A^*A)^{1/2}$ a proper choice of $\varepsilon$ is $\varepsilon < 1/\text{cond}_2(A)$, where $\text{cond}_2(A) = \|A\|_2 \cdot \|A^+\|_2$ is the condition number of $A$. But since the condition number is mostly unknown, a proper choice of $\varepsilon$ is difficult, but not if the singular value decomposition of a matrix is used for determining the rank. See also Golub, Klem, Stewart [19]. In order to determine the minimum rank by transformation into normal form we have to check whether the pivots are smaller than a tolerance $\delta$ which depends on the number of digits of the computer and the condition number. This procedure is practicable, although it can fail in sophisticated counter-examples, cf. Peters, Wilkinson [37].

In our computations, which were done on a R 300 computer (8 decimal digits), and for the test matrices used the following orders of $\delta/\|A\| = \varepsilon$ proved to be feasible:

- $\varepsilon$ between $10^{-8}$ and $10^{-5}$ for matrices with condition numbers up to about $10^8$ ("well-conditioned"),
- $\varepsilon$ about $10^{-8}$ for matrices with larger condition numbers ("ill-conditioned").

We used the Frobenius norm $\|A\|_F = \sqrt{\sum_i \sum_j |a_{ij}|^2}$. It is advisable for matrices which are not known to be well-conditioned to check the correctness of the computations (and hence the correct determination of the rank) by inserting the computed $A^+$ into the Penrose equations.

8. Solution of the matrix equation $AXB = C$

**Theorem 6.** For the solution of the matrix equation $AXB = C$ the following results hold, in which $X$ is an arbitrary matrix of suitable size.

Condition of consistency (necessary and sufficient for the solvability of $AXB = C$):

(1) \[ C = AA^+CB^+B. \]

General solution of the homogeneous system $AXB = 0$:

(2) \[ X = Y - A^+AYBB^+. \]

General solution of the consistent inhomogeneous system $AXB = C$:

(3) \[ X = A^+CB^+ + Y - A^+AYBB^+. \]

Minimum norm solution (solution of $\|X\|_F = \min_{AXB=C}$):

(4) \[ X = A_+^1CB_+^{1.3}. \]
General least-squares solution (solution of $\|AXB - C\|_F = \min_X$):

$$X = A^{1/4}CB^{1/4} + Y - A^{-1}AYBB^{-1}.$$  \hfill (5)

Best approximate solution (solution of $\|X\|_F = \min_X$, $K = \{X | \|AXB - C\|_F = \min\}$):

$$X = A^+CB^+.$$  \hfill (6)

Remark. (1), (2), (3) are due to Penrose [35], (4) to Hearon [24], (5) to Zielke [53], (6) to Penrose [36]. In order to solve $AXB = C$ numerically the matrices $A$ and $B$ can be transformed into normal form and then the generalized inverses required can be computed according to Theorem 4.

9. Computation of column spaces, null spaces and projectors

A further application of the transformation into normal form.

**Theorem 7.** Let $A \in \mathbb{C}^{m \times n}$ of rank $r$ be transformed into the normal form $PAQ = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}$ by the nonsingular matrices $P = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix}$ and $Q = (Q_1, Q_2)$ as in Theorem 4. Then we obtain: the bases

1. $B_{R(A)} = AQ_1$ basis for the column space of $A$ ($r$ linear independent columns of $A$),
2. $B_{N(A)} = Q_2$ basis for the null space of $A$ ($x = Q_2y$ is the general solution of the homog. system $Ax = 0$),
3. $B_{R(A^*)} = (P_1A)^*$,
4. $B_{N(A^*)} = P_2^*$;
5. the orthogonal projectors

$$P_{R(A)} = AQ_1(AQ_1)^+ \text{ orthogonal projector on } R(A)$$

$$= AQ_1[(AQ_1)^*AQ_1]^{-1}(AQ_1)^*$$

$$= I_m - P_{N(A^*)},$$  \hfill (r \leq m/2)

$$P_{N(A)} = Q_2Q_2^+ = Q_2(Q_2^*Q_2)^{-1}Q_2^*$$

$$= I_n - P_{R(A^*)},$$  \hfill (r \geq n/2)

$$P_{R(A^*)} = (P_1A)^+P_1A = (P_1A)^*[P_1A(P_1A)^*]^{-1}P_1A$$

$$= I_n - P_{N(A)},$$  \hfill (r \leq n/2)

$$P_{N(A^*)} = P_2^+P_2 = P_2^*(P_2P_2^*)^{-1}P_2$$

$$= I_m - P_{R(A)}.$$  \hfill (r \leq m/2)

**Proof.** See Zielke [49].
Remark. The inequalities \( r < m/2 \) etc. refers only to the smallest computational amount, but not to a limitation of the validity.

10. Other methods for computing generalized inverses

Main method: Full-rank factorization (Egerváry [16], Greville [23]).

**Theorem 8.** Any matrix \( A \in C^{m \times n} \) of rank \( r \) can be expressed as a product

\[
A = BC, \quad \text{where} \quad B \in C^{m \times r} \text{ and } C \in C^{r \times n}
\]

are full-rank matrices, both of rank \( r \). Then

\[
A^+ = C^+B^+ \quad \text{with} \quad C^+ = C^*(CC^*)^{-1}, \quad B^+ = (B^*B)^{-1}B^*.
\]

**Procedures:**

1. **LU decomposition** (Kublanowskaja [26], Peters, Wilkinson [37])

\[
A = LU = \begin{bmatrix}
L & \text{lower trapezoidal, with units on the principal diagonal,} \\
U & \text{upper trapezoidal.}
\end{bmatrix}
\]

Computation of \( L \) and \( U \) by means of Gauss elimination.

Note: Usually, the decomposition is performed along with some form of pivoting (interchanging rows and/or columns), that means, in reality we start from a matrix \( \bar{A} \) and obtain the factorization

\[
T_1 \bar{A} T_2 = A = LU,
\]

where \( T_1 \) and \( T_2 \) are permutation matrices. Then

\[
A^+ = U^+L^+ = U^*(UU^*)^{-1}(L^*L)^{-1}L^*.
\]

First, compute \( X \) from \( L^*LX = L^* \), \( Y \) from \( UU^*Y = X \), then \( A^+ = U^*Y \) and \( \bar{A}^+ = T_1A^+T_2 \).

2. **Orthogonal decomposition**

\[
A = QR,
\]

\( Q \): orthonormal columns, i.e. \( Q^*Q = I_r \), \( R \): upper trapezoidal.

Computation of \( Q \) and \( R \) by means of Householder transformation (Korganoff, Pavel-Parvu [25] or modified Gram–Schmidt orthogonalization (Osborne [34]) or Givens method (Kublanowskaja [26]). Then,

\[
A^+ = R^*(RR^*)^{-1}Q^*.
\]

3. **Singular value decomposition** (Golub, Kahan [18])

\[
A = USV^* = \sum_{i=1}^{r} \sigma_i u_i v_i^*,
\]
\[ S = \text{diag}(\sigma_1, \ldots, \sigma_r), \quad \sigma_i = \sqrt{\lambda_i(A^*A)} > 0 \text{ singular values of } A, \]
\[ U = (u_1, \ldots, u_r), \quad V = (v_1, \ldots, v_r) \text{ with orthonormal columns } u_i, v_i \]
(singular vectors, the eigenvectors of \( AA^* \) and \( A^*A \), respectively, corresponding to the eigenvalues \( \lambda_i \neq 0 \) of \( A^*A \) (or \( AA^* \)).

Then
\[ A^+ = VS^{-1}U^* = \sum_{i=1}^{r} \frac{1}{\sigma_i} v_i u_i^*. \]

**Note.** If the computer yields \( S = \text{diag}(\sigma_1, \ldots, \sigma_n), \quad \sigma_1 \geq \ldots \geq \sigma_n \), then \( A \) has minimal rank \( r(A) = r \) relative to \( \| \cdot \|_2 \) if and only if
\[ \frac{\sigma_{r+1}}{\sigma_1} \leq \varepsilon < \frac{\sigma_r}{\sigma_1} = \frac{1}{\text{cond}_2(A)}, \]

compare Golub, Klema, Stewart [19]. That means, all the singular values \( \sigma_i, \quad i = r+1, \ldots, n, \) for which \( \sigma_i \leq \varepsilon \sigma_1 \) holds must be set equal to zero.

A reasonable choice of \( \varepsilon \) is \( \varepsilon = \eta \) where \( \eta \) is the relative machine precision \( \eta = 0.5B^{-t+1} \) (t number of digits, \( B \) base of the number system).

4. **Block decomposition** (Noble [33]). Obviously, any matrix of known rank \( r < \min(m, n) \) can be partitioned into the block form
\[ A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \quad A_{11} \in \mathbb{C}^{r \times r} \text{ nonsingular,} \]

by interchanging rows and columns if necessary. Then, because of \( A_{22} = A_{21}A_{11}^{-1}A_{12} \), it holds
\[ A = \begin{bmatrix} A_{11} \\ A_{21} \end{bmatrix} A_{11}^{-1}(A_{11}, A_{12}), \quad A_i^- = \begin{bmatrix} A_{11}^{-1} & 0 \\ 0 & 0 \end{bmatrix}, \]
\[ A^+ = (A_{11}, A_{12})^+ A_{11} \begin{bmatrix} A_{11} \\ A_{21} \end{bmatrix}^+ \]
\[ = \begin{bmatrix} A_{11} \\ A_{12} \end{bmatrix} (A_{11}A_{11}^* + A_{12}A_{12}^*)^{-1}A_{11}(A_{11}^*A_{11} + A_{21}^*A_{21})^{-1}(A_{11}^*, A_{21}^*). \]

The general forms of the other generalized inverses can be found in Zielke [49], [52].

5. **Transformation into Hermite normal form**
\[ PAT = \begin{bmatrix} I_r & K \\ 0 & 0 \end{bmatrix}, \quad P \text{ nonsingular, } T \text{ permutation matrix.} \]

Computation of \( P, T, K \) by Gauss elimination. Then
\[ A^+ = T \begin{bmatrix} I_r \\ K^* \end{bmatrix} (I_r + KK^*)^{-1}(I_r, -P_T^*P_T^+)P \quad (\text{Zielke [49], [52]}). \]
The equation
\[(I_r + KK^*)^{-1} = I_r - K(I_n - r + K^*K)^{-1}K^*\]

can be used to reduce the computational amount if \(r\) is relatively large or small. We propose to use the left-hand side if \(r < \frac{1}{2}n\), otherwise the right-hand side. In this way and by a suitable choice of the succession of matrix multiplications it is possible to achieve for large \(m = n = r\) the minimal computational amount of about \(n^3\) multiplications.

6. Generalized iteration of Schulz (Ben-Israel [2], [3], Ben-Israel, Cohen [5]). Starting from
\[X_0 = aA^*, \quad 0 < a < \frac{2}{\lambda_{\text{max}}(A^*A)}, \quad \text{e.g.} \quad a = \frac{1}{\|A^*A\|},\]
the sequence
\[(*) \quad X_{k+1} = X_k + X_k(I - AX_k), \quad k = 0, 1, \ldots\]
converges to \(A^+\) as \(k \to \infty\). Practically, the algorithm needs at least \(2\log_2[\text{cond}_2(A)]\) iterations (e.g. \(\text{cond}_2(A) = 10^3 \Rightarrow k > 20\)).

Disadvantage of the method: not self-correcting, numerically divergent, not suitable for iterative refinement of an approximation to \(A^+\).

Remark. Any approximation \(X_0\) to \(A^+\) can be adapted to the space conditions \(X = YA^* = A^*Z\) (see Definition 3) by orthogonal projecting \(P_{R(A^+)}X_0P_{R(A^+)} = A^+AX_0A^+\). But the exact \(A^+\) is unknown.

An approximation \(X_0\) which exactly satisfies the space conditions can be obtained without knowing \(A^+\) by using the Penrose equations (P3) \(A^+A = A^*A^*\) and (P4) \(A^+A = A^*A^*\) and then replacing \(A^+\) by \(X_0\):
\[(**) \quad X_0 = A^*X^*_0X_0X^*_0A^*\].
The iterative method (*) with \(X_0\) as initial approximation converges to \(A^+\) if \(X_0\) is a sufficiently close approximation to \(A^+\) and \(\text{cond}(A)\) is not too large. In order to improve the accuracy compared with that obtained by a good direct method the iterative process must be performed in double precision arithmetic. This process is self-correcting if the (oblique) projection (**) is repeated after some iterations (Zielke [50]). See also Shinozaki, Sibuya, Tanabe [43], [44].

11. Test matrices and numerical results
More than 30 methods for computing \(A^+\) were tested by test matrices whose condition numbers can be changed by a real or complex par-
ameter $a$. Three of the simplest matrices are the following:

$$A_1 = \begin{bmatrix} a & a & a-1 & a \\ a+1 & a & a & a \\ a & a & a-1 & a \\ a+1 & a & a & a+1 \end{bmatrix}, \quad A_1^+ = \frac{1}{4} \begin{bmatrix} 2a & 2 & 2a & 2 \\ 0 & -1 & 0 & -1 \\ 0 & -1 & 0 & -1 \\ -2a-2 & 0 & -2a-2 & 0 \end{bmatrix},$$

$$\text{rank}(A_1) = 3,$$

$$\text{cond}_F(A_1) = \begin{array}{c|c|c|c|c|c} \hline a & 0 & 1 & 10 & 10^2 & 10^3 \\ \hline \text{cond}_F(A_1) & 3.5 & 14 & 8.0_{10^2} & 7.8_{10^4} & 7.8_{10^6} \\ \hline \end{array}$$

$$A_2 = \begin{bmatrix} a+1 & a & a & a+1 \\ a+2 & a+1 & a+1 & a+2 \\ a+3 & a+2 & a+2 & a+3 \\ a+1 & a+1 & a+2 & a+2 \end{bmatrix},$$

$$A_2^+ = \frac{1}{60} \begin{bmatrix} 12a+44 & 20 & -12a-4 & -6a-27 & 6a-3 \\ -12a-56 & -20 & 12a+16 & 6a+33 & -6a-3 \\ -12a-12 & 0 & 12a+12 & 6a-9 & -6a-21 \\ 12a & 0 & -12a & -6a+15 & 6a+15 \end{bmatrix},$$

$$\text{rank}(A_2) = 3,$$

$$\text{cond}_F(A_2) = \begin{array}{c|c|c|c|c|c} \hline a . & 0 & 1 & 10 & 10^2 & 10^3 \\ \hline \text{cond}_F(A_2) & 11 & 21 & 3.7_{10^2} & 2.9_{10^4} & 2.8_{10^6} \\ \hline \end{array}$$

$$A_3 = \begin{bmatrix} a & a+1 & a+2 & a+3 & a \\ a & a+2 & a+3 & a+5 & a+1 \\ a+1 & a+2 & a+3 & a+4 & a+2 \\ a+2 & a+3 & a+4 & a+5 & a+3 \\ a+3 & a+4 & a+5 & a+6 & a+5 \\ a+5 & a+6 & a+6 & a+7 & a+7 \end{bmatrix},$$

$$A_3^+ = \frac{1}{6} \begin{bmatrix} 4 & -1 & -8 & 7 & -5 & 3 \\ -8 & 2a+13 & -8a-28 & 6a+17 & -2a-3 & 2a+1 \\ 10 & -2a-11 & 8a+18 & -6a-9 & 2a-1 & -2a+1 \\ -2 & 3 & -2 & 1 & 1 & -1 \\ -4 & -2 & 12 & -10 & 6 & -2 \end{bmatrix},$$

$$\text{rank}(A_3) = 4,$$

$$\text{cond}_F(A_3) = \begin{array}{c|c|c|c|c} \hline a & 0 & 1 & 10 & 10^2 & 10^3 \\ \hline \text{cond}_F(A_3) & 1.3_{10^2} & 2.0_{10^2} & 1.8_{10^3} & 1.1_{10^5} & 1.0_{10^7} \\ \hline \end{array}$$

**Numerical results.** For each tested method and each of the test matrices the "minimum number of correct decimal digits", i.e. the quantity

$$-\log_{10}(\text{maximum relative error}) = -\log_{10} \left[ \max_{\varphi_{ij} \neq 0} \left| \frac{\tilde{g}_{ij} - g_{ij}}{g_{ij}} \right| \right]$$
was determined, where $\tilde{g}_{ij}$ is the computed value of the element $g_{ij}$ of $A^+=g_{ij}$. If $g_{ij}=0$ then the maximum absolute error was used. Of course, $\tilde{g}_{ij}=g_{ij}$ $\forall i, j$ means full precision.

**Abbreviations:**

- rank false, · rank correct
- Lim $A^+=\lim_{\epsilon \to 0} (A^-A+\epsilon I)^{-1}A^*$

GREV Grevelle’s method (successive bordering of columns)
Iter Iterative method of Ben-Israel
SVD Singular value decomposition
GIV Givens’ method
MGS Modified Gram–Schmidt orthogonalization
HOUS Householder’s method
LU LU decomposition (Gauss elimination)
HT Transformation into Hermite normal form

**Table. Number of correct decimal digits (8 decimal digits mantissa)**

**Precision:**

very poor  poor  good  good or very good

**Remarks.** 1. Op$(n^3)$: number of multiplications for $m=n=r \gg 1$, only of order $n^3$, $A$ real, $k$: number of iterations.
2. The transformation into normal form ($\frac{3}{2} n^2$ op.) yields results similar to LU decomposition.

3. Concerning the rank test, SVD is the most reliable method.

12. Final remarks

12.1. Short historical notes. The theory of generalized inverses of matrices has been developed during the past 25 years caused by two papers by R. Penrose [35], [36] (generalized inverse $A^+$) who showed that the least squares solution of the inconsistent system $Ax = b$ with the smallest Euclidean norm is given by $x = A^+b$.

Already previously, E. H. Moore [29], [30] (general reciprocal) obtained fundamental results on generalized inverses, probably much earlier, about in 1906, see Ben-Israel, Greville [6], p. 5.

Extension to generalized inverses of linear operators in Hilbert space by Y. Y. Tseng [46]–[48] a student of Moore.

The concept of a generalized inverse was already mentioned by I. Fredholm [17] (pseudoinverse of a linear integral operator).

Further main contributions to generalized inverses of matrices were made, among others, by:
A. Bjorhammar [7], [8] (different types of generalized inverses, application to linear systems),
T. N. E. Greville [22], [23] (fundamental papers),
C. R. Rao [39], [40] (classification of generalized inverses),

Generalized inverses solve linear algebraic systems. But there are other generalizations of inverses, for instance the Drazin inverse (Drazin [15], see also Campbell, Meyer [13]) which can solve systems of linear differential and difference equations. But how to compute the Drazin inverse?

12.2. References to books and algorithms:
Korganoff, Pavel-Parvu [25] (earliest book on generalized inverses, extensive bibliography, detailed treatment of numerical methods),
Boullion, Odell [11] (proceedings of a symposium, comprehensive bibliography),
Boullion, Odell [12] (textbook, containing exercises and 362 references),
Pringle, Rayner [38] (accurately written monograph with statistics applications),
Rao, Mitra [41] (full-length monograph, concise style, several applications of generalized inverses, especially in statistics),
Albert [1] (textbook with applications in statistics, restricted to the
Moore–Penrose inverse, numerous problems with solutions in a separate
booklet),
Björk [9] (generalized inverses are treated only to a shorter extent,
the terminology used is not up to date),
Ben-Israel, Greville [6] (a comprehensive and very well readable book
with more than 450 exercises, containing a chapter on generalized
inverses of linear operators in Hilbert spaces),
Kuhnert [27] (short introduction to the solution of linear equations by
means of the Moore–Penrose inverse, regularization methods are also
considered),
Nashed [32] (proceedings of an advanced seminar, collection of excellent
survey papers, containing the most comprehensive annotated bibli-
ography on generalized inverses and applications, 1776 references),
Groetsch [21] (representation and approximation of generalized inverses
of linear operators in Hilbert spaces),
Campbell, Meyer [13] (well-written unified treatment of generalized
inverses including the theory and applications of Drazin inverses).

In addition, two books are mentioned which use generalized inverses
in connection with the numerical solution of linear equations:
Stewart [45] (introduction to matrix computation, textbook),
Lawson, Hanson [28] (detailed numerical treatment of least-squares
problems).

Algorithms. Some algorithms and computer codes for computing
least-squares solutions and Moore–Penrose inverses of matrices of arbit-
rary rank, which are well elaborated and tested and highly recommended
in the literature, can be found in:
Björck [10] (modified Gram-Schmidt orthogonalization, ALGOL proce-
dures),
Golub, Reinsch [20] (singular value decomposition, ALGOL procedures),
Lawson, Hanson [28] (Householder transformation, singular value de-
composition, FORTRAN codes),
Dongarra, Bunch, Moler, Stewart [14] (Householder transformation
singular value decomposition, FORTRAN subroutines).
