INFINITESIMAL DEFORMATIONS
OF QUOTIENT SURFACE SINGULARITIES

A quotient surface singularity is determined by a finite group $G$ acting linearly on a two-dimensional complex vector space $V$ or, equivalently, by the corresponding action of $G$ on the local ring $\mathcal{O}_{V,0}$ of holomorphic functions at 0, respectively on the associated graded ring which is isomorphic to the polynomial ring $S = \mathbb{C}[u, v]$. As a general philosophy, all analytic, algebraic, geometric and topological invariants associated to the singularity $X = (V/G, 0)$ should be computable by those or by corresponding actions. For instance, Henry Pinkham has shown in [7] how one can describe the vector space $T^1_X$ of (isomorphism classes of first order) infinitesimal deformations of $X$ by the invariants of the action of $G$ on $S$ and on the cohomology groups

$$H^1(V \setminus \{0\}, \mathcal{O}_V) \quad \text{and} \quad H^1(V \setminus \{0\}, \Theta_V)$$

(where $\Theta_V$ denotes the sheaf of germs of holomorphic vector fields on $V$), using a result of Schlessinger ([10]) on $T^1_X$ for an arbitrary normal surface singularity $(X, x)$. He was able to present a basis for $T^1_X$ in the case of a cyclic group, reestablishing a dimension formula of the last author ([8]), and two of the authors of the present note used his method to find such a basis.
for the class of "dihedral" singularities ([2]). However, in the remaining cases it seemed to be hopeless to calculate $T^1_X$ by the same method, even in the case of the binary polyhedral groups $T, O, I$ (i.e., the finite subgroups of $\text{SL}(2, \mathbb{C})$), where the dual of $T^1_X$ can easily be gotten from a defining equation $R(x, y, z) = 0$ for $X$ by the isomorphism

$$(T^1_X)^* \cong C[x, y, z]/\left( R, \frac{\partial R}{\partial x}, \frac{\partial R}{\partial y}, \frac{\partial R}{\partial z} \right).$$

In a first version of this paper written in 1983 it was shown how one can find a basis of the invariant vector spaces

$$H^1(V \setminus \{0\}, \mathcal{O}_V)^G \quad \text{and} \quad H^1(V \setminus \{0\}, \Theta_V)^G$$

for finite groups $G \subset \text{GL}(2, \mathbb{C})$ in a canonical way via easily computable invariants like $S^G$. Here, we used the fact that the whole general linear group $\text{GL}(2, \mathbb{C})$ acts on the cohomology groups envolved, especially by applying the Clebsch–Gordan formulas. With these bases and generators of $S^G$, it is possible to determine explicitly the linear mappings which enter the description of $T^1_X$ by Pinkham, making his result a little more concrete (Theorem 1). However, from the computational point of view, the systems of linear equations one obtains this way, are still not tractable, unless one has a priori bounds for the degrees of the base elements of $T^1_X$ or one knows the dimension of $T^1_X$ (as in the case of quotients by the binary polyhedral groups, i.e., for the rational double points).

It was remarked by Horst Knörrer that our results become much smoother, if one applies them to the dual space $(T^1_X)^*$: Using elementary duality for $\text{GL}(2, \mathbb{C})$-modules, we deduce from Pinkham's result a description of $(T^1_X)^*$ as the cokernel of a natural mapping (Theorem 2). This result, however, is only a special case of a general formula for $(T^1_X)^*$ in the case of an arbitrary normal surface singularity $(X, x)$ which was obtained by H. Knörrer and the first author in [1] by dualizing Schlessinger's description of $T^1_X$. Working on the resolution of the singularity $(X, x)$, they were able to determine the dimension of $T^1_X$ for a fairly wide class of rational singularities including the quotient singularities with the exception of 63 individual cases with low embedding dimension. On the other hand, the second author found an algorithm for computing the dimension of $T^1_X$ for all series of quotient surface singularities, using only invariant theory ([5]). We include his tables which were obtained with the aid of a personal computer at the end of Section 7 of this paper.

Applying again the Clebsch–Gordan isomorphisms we get a natural splitting of $(T^1_X)^*$ into two parts (Theorem 3). For rational double points, the second part is trivial and the first part identifies (see Section 5) with

$$(2) \quad S^G/\text{ideal generated by all Jacobians } J(f_1, f_2), f_1, f_2 \in S^G,$$
where
\[ J(f_1, f_2) = \det \begin{bmatrix} \partial_u f_1 & \partial_v f_1 \\ \partial_u f_2 & \partial_v f_2 \end{bmatrix}. \]

Of course, formula (2) can easily be deduced from (1). Moreover, we should mention that (2) is only a special case of a formula due to J. Wahl ([15]) which holds for all quasi-homogeneous Gorenstein surface singularities \((X, x)\): In this case, \(S^g\) has to be replaced by the dualizing module \(\omega_{X, x}\) of the singularity and the ideal by the module generated by all exterior products \(df_1 \wedge df_i\) for functions \(f_1, \ldots, f_i\) generating the maximal ideal \(m_{X, x}\) of the local ring \(O_{X, x}\). So, denoting by \(\Omega^1_{X, x}\) the \(O_{X, x}\)-module of Kähler differentials at \(x \in X\), (2) should be interpreted as the canonical isomorphism
\[
(\mathcal{T}_X^1)^* \cong \omega_{X, x} / \text{image of } \Omega^2_{X, x}.
\]

Motivated by Wahl’s formula we generalize our splitting result in Section 8 to some finite quotients of quasi-homogeneous Gorenstein surface singularities (including all quasi-homogeneous rational singularities of embedding dimension \(e \geq 4\)) and show that the second part has always a dimension equal to \(\dim_{\mathbb{C}}(\omega_{X, x} / m_{X, x} \omega_{X, x})\), i.e., to the minimal number of generators for the dualizing module (which equals \(e - 2\) in the rational case).

In Section 6 we sketch two methods how one can deal, at least in principle, with the first part and apply the second one to the cyclic case. Finally, in Section 7, we compute this part for a complete series of quotients by the groups \(T \cdot (\mathbb{Z} / 2m\mathbb{Z})\), \(m = 6(b - 2) + 1, b \geq 3\), and list the results of [5].

We want to thank the Max-Planck-Institut für Mathematik for supporting two of us (B. and K.) during the preparation of this paper. We are indebted to Horst Knörrer for many helpful conversations, suggestions and remarks on a first draft of our manuscript. Thanks are also due to J. Wahl whose useful comments on Section 8 are partly transformed into remarks. Of course, the responsibility for the content of the final version, especially for the decision to keep the whole paper in an extremely elementary spirit and not to use more sophisticated tools like, e.g., Auslander’s and Reiter’s almost split sequences, is completely ours.

1. Some standard \(\text{GL}(2, \mathbb{C})\)-modules

For the convenience of the reader and in order to fix our notations, we describe some well-known representations of the general linear group \(\text{GL}_2 = \text{GL}(2, \mathbb{C})\). We choose once and for all a basis \(e_1, e_2\) of the vector space \(V\) and let the group element
\[ g = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \in \text{GL}_2 \]
act on a vector \(ue_1 + ve_2\) by
\[
g(ue_1 + ve_2) = (\alpha u + \beta v)e_1 + (\gamma u + \delta v)e_2 = : u'e_1 + v'e_2,
\]
or, equivalently, by
\[
\begin{bmatrix}
u' \\
v
\end{bmatrix} = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \begin{bmatrix} u \\
v
\end{bmatrix}.
\]

This gives the standard left representation \(G \times V \to V\) which in turn yields a left representation on the dual vector space \(V^*\) by the condition
\[
\langle g(\lambda), g(w) \rangle = \langle \lambda, w \rangle, \quad \lambda \in V^*, \quad w \in V.
\]

This representation is given by \((g, \lambda) \mapsto \lambda \circ g^{-1}\) and will be described via the dual basis \(e_1^*, e_2^*\) by the contragredient matrix
\[
tg^{-1} = \frac{1}{\Delta(g)} \begin{bmatrix} \delta & -\gamma \\ -\beta & \alpha \end{bmatrix}, \quad \Delta(g) = \det g = \alpha \delta - \beta \gamma.
\]

Denoting as above coordinates of \(V\) by \(u\) and \(v\), we can interpret \(e_1^*\) and \(e_2^*\) as the coordinate functions which we will also denote by \(u\) and \(v\), respectively. So, we identify \(V^*\) with the vector space of linear functions \(au + bv, \ a, \ b \in \mathbb{C}\).

Having a representation on a vector space one can induce representations on the symmetric and exterior powers. In this note we use \(S_l\) for the \(l\)th symmetric power of \(V^*\):
\[
S_l = S_1(V^*)
\]
which we identify with the vector space of homogeneous polynomials of degree \(l\) in \(u\) and \(v\) with the basis
\[
e_{jk}^* = u^j v^k, \quad j+k = l.
\]

The action of \(GL_2\) on \(S_l\) is given by
\[
(5) \quad g(u^j v^k) = \frac{1}{\Delta(g)} (\delta u - \beta v)^j (\gamma u + \alpha v)^k
\]
and induces a \(\mathbb{C}\)-algebra representation of \(GL_2\) on the polynomial ring
\[
S = \bigoplus_{l=0}^{\infty} S_l = \mathbb{C}[u, v].
\]

More generally, if \(f \in \mathcal{O}_{V,0}\) is a germ of a holomorphic function at the origin, we can define \(g(f) = f \circ g^{-1} \in \mathcal{O}_{V,0}\) for all \(g \in GL_2\). In this way one gets a canonical left \(GL_2\)-representation which maps the \(l\)th power \(m^l\) of the maximal ideal \(m\) of \(\mathcal{O}_{V,0}\) into itself. Hence, this action induces a left representation of \(GL_2\) on the associated graded ring
\[
\text{Gr} \mathcal{O}_{V,0} = \bigoplus_{l=0}^{\infty} m^l/m^{l+1}
\]
which is - as \(GL_2\)-algebra - isomorphic to \(S\). One can look at this
isomorphism also from another point of view: The multiplicative group \( C^* \) acts via

\[
C^* \ni c \mapsto g_c = \begin{bmatrix} c & 0 \\ 0 & c \end{bmatrix} \in \text{GL}_2
\]
on every \( \text{GL}_2 \)-module \( M \), such that we have the eigenspaces

\[
M_l = \{ m \in M : g_c(m) = c^{-l} m \text{ for all } c \in C^*, \ l \in \mathbb{Z} \}
\]
of homogeneous elements of degree \( l \). Since the operations of \( C^* \) and \( \text{GL}_2 \) commute, \( \text{GL}_2 \) operates also on the associated graded module

\[
M_{gr} = \bigoplus_{l = -\infty}^{\infty} M_l
\]
and on the module

\[
M_+ = \bigoplus_{l = 1}^{\infty} M_l
\]
consisting of homogeneous elements of positive degree. Of course, in the case above, \( S_l \cong (\mathcal{O}_{V,0})_l \) and

\[
(\mathcal{O}_{V,0})_{gr} \cong \bigoplus_{l = 0}^{\infty} S_l \cong C[u, v] \cong \text{Gr} \mathcal{O}_{V,0}.
\]

For certain purposes it is convenient to identify \( V^* \) with the cotangent space of \( V \) at 0 via

\[
T_{V,0}^* \cong m/m^2 \cong S_1(V^*) \cong V^*
\]
where the differential \( du \) is mapped to \( e_1^* \) and \( dv \) goes to \( e_2^* \). If we provide \( T_{V,0}^* \) with the natural \( \text{GL}_2 \)-action

\[
g(d\lambda) = (d\lambda) \circ g^{-1} = d(\lambda \circ g^{-1}) = d(g(\lambda)),
\]
\( \lambda = au + bv, \ a, b \in \mathbb{C} \), this isomorphism is \( \text{GL}_2 \)-equivariant. Dualizing again, we get a \( \text{GL}_2 \)-isomorphism

\[
V \cong T_{V,0}
\]
where \( e_1 \mapsto \partial_u = \frac{\partial}{\partial u}, \ e_2 \mapsto \partial_v = \frac{\partial}{\partial v} \). We denote by

\[
S^* = \bigoplus_{l = 0}^{\infty} S_l^*, \quad S_l^* = S_l(T_{V,0})
\]
the algebra of linear differential operators with constant coefficients:

\[
\partial \in S_l^* \iff \partial = \sum_{j+k=l} a_{jk} \partial_u^j \partial_v^k
\]
with the $GL_2$-action given by
\begin{equation}
(7) \quad g(\partial_u^j \partial_v^k) = (\alpha \partial_u + \gamma \partial_v)^j (\beta \partial_u + \delta \partial_v)^k.
\end{equation}

$S^*_\gamma$ is in a canonical way the dual of $S_\gamma$, the pairing being given by
\[
\langle \partial_u^j \partial_v^k, u^l v^m \rangle = \begin{cases} j! k!, & \text{if } j = 1, k = \lambda, \\ 0, & \text{otherwise}. \end{cases}
\]

Finally, since
\[
g(du \wedge dv) = g(du) \wedge g(dv) = \frac{1}{\Delta(g)^2} (\delta du - \beta dv) \wedge (-\gamma du + \alpha dv),
\]
we get on $\Lambda^2 T_{\gamma,0}^*$ the representation
\begin{equation}
(8) \quad g(du \wedge dv) = \Delta(g)^{-1} du \wedge dv,
\end{equation}
and on $\Lambda^2 T_{\gamma,0}$ there is the dual representation
\begin{equation}
(9) \quad g(\partial_u \wedge \partial_v) = \Delta(g) \partial_u \wedge \partial_v.
\end{equation}

Now, for any $GL_2$-module $M$, there is a natural action of $GL_2$ on $M \otimes \Lambda^2 T_{\gamma,0}^*$, identifying this tensor product with $M$ via $m \mapsto m \otimes (du \wedge dv)$, we get a new action on $M$ which is given by
\[
(g, m) \mapsto \chi(g) \cdot g(m).
\]
Here $\chi$ stands for the character
\begin{equation}
(10) \quad \chi: \quad GL_2 \to C^\ast, \quad \chi(g) = \Delta(g)^{-1}.
\end{equation}

To distinguish the new $GL_2$-module from the old one, we denote it by $M_\chi$.

In the same manner we construct $M_{\chi,k}$ for all $k \in \mathbb{Z}$.

We notice that there exists a natural isomorphism $V^\ast \cong V \otimes \Lambda^2 V^\ast$ given in coordinates by $e_1^* \mapsto e_2 \otimes (e_1^* \wedge e_2^*)$, $e_2^* \mapsto -e_1 \otimes (e_1^* \wedge e_2^*)$. Hence, it induces isomorphisms of $GL_2$-modules $S_l \cong S_{l,\chi}$ by
\begin{equation}
(11) \quad u^j v^k \mapsto (-1)^k \partial_u^j \partial_v^k, \quad j + k = l.
\end{equation}

2. The $GL_2$-modules $H^1(V \setminus \{0\}, \xi_\gamma)$ and $H^1(V \setminus \{0\}, \Theta_\gamma)$ and their duals

We realize cohomology classes on $U := V \setminus \{0\}$ by 1-cocycles via the canonical isomorphism
\[
H^1(U, \mathcal{F}) \cong H^1(\mathcal{W}, \mathcal{F}) = Z^1(\mathcal{W}, \mathcal{F})/B^1(\mathcal{W}, \mathcal{F})
\]
which holds for any coherent analytic sheaf $\mathcal{F}$ on $U$ and for arbitrary Stein coverings $\mathcal{W} = \{W_\sigma\}_{\sigma \in \Sigma}$ of $U$. So, we write for a cohomology class $\xi \in H^1(U, \mathcal{F})$:
\[
\xi = [f_\sigma], \quad f_\sigma \in H^0(W_\sigma \cap W_\tau, \mathcal{F}).
\]
For $\mathcal{F} = \mathcal{O}_V$, $\text{GL}_2$ acts on the first cohomology group as follows: If $\xi = \lbrack f_\sigma \rbrack$, $f_\sigma \in H^0(W_\sigma \cap W, \mathcal{O}_V)$, then

$$g(\xi) = \lbrack f_\sigma \circ g^{-1} \rbrack = \lbrack g(f_\sigma) \rbrack$$

where $g(f_\sigma) \in Z^1(g(\mathcal{W}), \mathcal{O}_V)$, $g(\mathcal{W}) = \{g(W_\sigma)\}_{\sigma \in \Sigma}$. It is easily seen that this action is independent of the Stein covering $\mathcal{W}$. Using in the following the special covering $\mathcal{U} = \{U_1, U_2\}$ with

$$U_1 = \{(u, v): u \neq 0\}, \quad U_2 = \{(u, v): v \neq 0\},$$

it is immediately clear that an element

$$g_1 = \begin{bmatrix} \alpha & 0 \\ 0 & \delta \end{bmatrix} \in \text{GL}_2$$

acts on the special class

$$\xi_{jk} = \begin{bmatrix} 1 \\ u^{j+1} v^{k+1} \end{bmatrix}, \quad j, k \geq 0$$

by

$$g_1(\xi_{jk}) = \alpha^{j+1} \delta^{k+1} \xi_{jk}. \quad (12)$$

So, by our conventions, $\xi_{jk}$ is homogeneous of negative degree $-(j+k+2)$, and it is well known that the $\xi_{jk}$ with fixed $l = j+k$ form a basis of the homogeneous part of $H^1(U, \mathcal{O}_V)$ of degree $-(l+2)$. In the following we write

$$H^1(U, \mathcal{O}_V)_{\text{gr}} := \bigoplus_{l=0}^\infty H^1(\mathcal{O}_V)_{-(l+2)}$$

and determine the structure of the $\text{GL}_2$-modules $H^1(\mathcal{O}_V)_{-(l+2)}$. To do this we have to compute the action of the special matrices

$$g_2 = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \quad \text{and} \quad g_3 = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix},$$

which together with the matrices $g_1$ generate the group $\text{GL}_2$. In the case of $g_2$ we have $g_2(\mathcal{U}) = \{U_2, U_1\}$, $g_2(u) = v$, $g_2(v) = -u$, and therefore

$$g_2(\xi_{jk}) = (-1)^{k+1} \begin{bmatrix} 1 \\ u^{k+1} v^{j+1} \end{bmatrix} \quad (\text{with respect to } g_2(\mathcal{U})) \quad (13)$$

$$= (-1)^k \xi_{kj}.$$ 

By the following calculation (which explains itself):

$$\frac{1}{(u-v)^{j+1} v^{k+1}} = \frac{1}{u^{j+1} v^{k+1}} \sum_{\lambda=0}^\infty \frac{(-j-1)}{\lambda} (-1)^\lambda \frac{v^\lambda}{u^\lambda}$$

$$= \frac{1}{u^{j+1} v^{k+1}} \sum_{\lambda=0}^\infty \frac{j+\lambda}{\lambda} \frac{v^\lambda}{u^\lambda},$$
we finally get
\begin{equation}
g_3(\xi_{jk}) = \left[ \frac{1}{(j + 1)(k + 1)} \right] \quad \text{(with respect to } g_3(\%))
\end{equation}
\begin{equation}
= \sum_{i=0}^{k} \binom{j + i}{i} \xi_{j + i,k - i}.
\end{equation}

We are now able to prove

**Lemma 1.** The \( C \)-linear isomorphism
\[
\varphi: S_{i,x}^* \rightarrow H^1(\mathcal{O}_{U}(-l+1_x))
\]
defined by
\begin{equation}
\varphi(\xi_{jk}) = \xi_{jk}, \quad \partial_{jk} = \frac{1}{j! k!} \partial_u^{j} \partial_v^{k}
\end{equation}
is \( GL_2 \)-equivariant.

**Proof.** We have to show that \( g_r \circ \varphi = \varphi \circ g_r \) for \( r = 1, 2, 3 \), which is trivial in the first two cases. For the last case this results from the following elementary computation:
\begin{align*}
(g_3 \circ \varphi)(\partial_u^{j} \partial_v^{k}) &= j! k! \sum_{i=0}^{k} \binom{j + i}{i} \xi_{j + i,k - i} \\
&= \sum_{i=0}^{k} \frac{j! k!}{(j + i)! (k - i)!} \binom{j + i}{i} \varphi(\partial_u^{j+i} \partial_v^{k-i}) \\
&= \varphi(\sum_{i=0}^{k} \binom{k}{i} \partial_u^{j+i} \partial_v^{k-i}) \\
&= \varphi(\partial_u^{j} \partial_v^{k}) \quad \square
\end{align*}

This result can be explained (and could have been derived) more naturally in the following way: Denote by \( \Omega_{\mathcal{V}}^2 \) the sheaf of germs of holomorphic 2-forms such that as \( GL_2 \)-modules
\[
H^0(V, \Omega_{\mathcal{V}}^2) \cong H^0(V, \mathcal{O}_V) \otimes \Lambda^2 T_{V,0}^*
\]
and
\[
H^0(V, \Omega_{\mathcal{V}}^2)_{gr} \cong \bigotimes_{l=0}^{\infty} S_{l,x} \cong \bigoplus_{l=0}^{\infty} S_{l,x}^* \cong \bigoplus_{l=0}^{\infty} S_{l,x}^* \cong \bigoplus_{l=0}^{\infty} S_{l,x}^* \cong \bigoplus_{l=0}^{\infty} S_{l,x}^*.
\]
So, Lemma 1 establishes a concrete \( GL_2 \)-equivariant pairing
\[
H^0(V, \Omega_{\mathcal{V}}^2)_{gr} \times H^1(U, \mathcal{O}_U)_{gr} \rightarrow C,
\]
\[
\text{sending } (u^i v^k) \otimes (du \wedge dv) \times \xi_{i,k} \text{ to } 1, \text{ if } i = j + 1, \text{ and to } 0 \text{ otherwise.}
\]
This pairing is induced, of course, by the natural residue pairing
\[ H^0(V, \Omega^2_V) \times H^1(U, \mathcal{O}_V) \to C \]
associating to each pair \( \omega = h du \wedge dv, \xi = \{f_{12}\} \) the residue of \( f_{12} h du \wedge dv \)
at the origin (in the sense of [4], p. 649 ff.) This pairing can be understood
even in a more conceptual framework. By the long exact sequence for local
cohomology and Theorem B for Stein manifolds, we get an exact sequence
\[ 0 = H^1(V, \mathcal{O}_V) \to H^1(U, \mathcal{O}_V) \to H^1_{\Omega^1}(\mathcal{O}_V) \to H^2(V, \mathcal{O}_V) = 0, \]
and by local duality we have a canonical isomorphism
\[ H^1_{\Omega^1}(\mathcal{O}_V)^* \cong \text{Hom}_{\mathcal{O}_V}(\mathcal{O}_V, \Omega^1_V) \cong H^0(V, \Omega^1_V). \]
We remark that, by the same reasoning, one gets natural isomorphisms
\[ H^1(X', \mathcal{F})^* \cong H^0(X', \mathcal{F}^* \otimes \Omega^2_{X'}) \]
where \( X \) is a normal two-dimensional Stein space with exactly one isolated
singularity \( x \), \( X' = X \setminus \{x\} \) and \( \mathcal{F} \) is a coherent reflexive sheaf on \( X \).
In order to calculate the \( GL_2 \)-module \( H^1(U, \Theta_V)_{gr} \), we observe that
\[ H^1(U, \Theta_V) \cong H^1(U, \mathcal{O}_V) \otimes T_{V,0} \]
as \( GL_2 \)-modules. Hence, we have a \( GL_2 \)-equivariant isomorphism
\[ \psi: S^*_{l-1,x-2} \otimes S^*_{l+1,x-1} \cong H^1(U, \Theta_V)_{gr} \]
given by \( \psi(P \otimes \delta) = \varphi(P) \otimes \delta \). But, by the classical Clebsch–Gordan
isomorphisms (which can be found in [11] and explicitly in [12], e.g.), we have
\[ S^*_{l-1,x-2} \otimes S^*_{l+1,x-1} \cong S^*_{l,x-1} \otimes S^*_{1} \]
for \( l \geq 0 \) where the isomorphism is given in the form \( \delta \otimes \iota \) with
\begin{align*}
\delta(\partial_u^j \partial_v^k) &= \partial_u^j \partial_v^{k+1} \otimes \partial_u^{j+1} \partial_v^k \otimes \partial_v, \quad j + k = l - 1, \\
\iota(\partial_u^j \partial_v^k) &= j \partial_u^{-1} \partial_v \otimes \partial_u + k \partial_u \partial_v^{k-1} \otimes \partial_v, \quad j + k = l + 1.
\end{align*}
(16)
Since elements in \( S^*_{l} \) have degree \( -l \), \( H^1(U, \Theta_V)_{gr} \) has only negatively graded
homogeneous parts:
\[ H^1(U, \Theta_V)_{gr} := \bigoplus_{l=0}^\infty H^1(\Theta_V)_{-(l+1)}. \]
Combining our results we finally get

**Proposition 1.** The \( C \)-linear isomorphism
\[ D^* \otimes I^* : S^*_{l-1,x-2} \oplus S^*_{l+1,x-1} \to H^1(\Theta_V)_{-(l+1)}, \]
given by
\[ D^* (\partial_{jk}) = (k + 1) \xi_{j,k+1} \otimes \partial_u - (j + 1) \xi_{j+1,k} \otimes \partial_v, \quad j + k = l - 1, \]
and
\[ I^* (\partial_{jk}) = \xi_{j-1,k} \otimes \partial_u + \xi_{j,k-1} \otimes \partial_v, \quad j + k = l + 1, \]
is \( \text{GL}_2 \)-equivariant for all \( l \geq 0 \).

Again, it is interesting to note that the dual version is much easier to describe. We notice first that
\[ H^1 (U, \Omega^*_V)^* \cong (H^1 (U, \mathcal{O}_V) \otimes T_{V,0})^* \cong H^0 (V, \Omega^2_V) \otimes T^*_{V,0} \]
\[ \cong H^0 (V, \Omega^1_V \otimes \Omega^1_V), \]
where \( \Omega^1_V \) denotes the sheaf of germs of holomorphic 1-forms on \( V \). Hence, by Proposition 1 there is a \( \text{GL}_2 \)-equivariant isomorphism of vector spaces
\[ H^0 (V, \Omega^1_V \otimes \Omega^1_V)_{gr} \cong H^0 (V, \Omega^1_V \otimes \Omega^1_V)_{gr} \oplus H^0 (V, \Omega^2_V)_{gr}. \]
It is easy to check that this isomorphism is induced by an isomorphism
\[ H^0 (V, \Omega^1_V)_{gr} \cong H^0 (V, \Omega^2_V)_{gr} \oplus H^0 (V, \mathcal{O}_V) \]
which is given, if represented in the form
\[ \omega = f du + g dv \mapsto (D(\omega), I(\omega)), \]
by differentiation
\[ D(\omega) = d\omega = df \wedge du + dg \wedge dv = (\partial_u g - \partial_v f) du \wedge dv \]
and integration
\[ I(\omega) = uf + vg. \]

So, we have proved the following version of the Clebsch–Gordan isomorphism:

**Proposition 2.** The \( C \)-linear mappings
\[ H^0 (V, \Omega^1_V)_{gr} \to S_2 \oplus S_+, \]
\[ H^0 (V, \Omega^1_V \otimes \Omega^1_V)_{gr} \to S_2 \oplus S_+ \]
defined by
\[ (f du + g dv) \mapsto (\partial_u g - \partial_v f, uf + vg), \]
\[ (f du + g dv) \otimes (hdv + dv) \mapsto (\partial_u (hg) - \partial_v (hf), h(uf + vg)) \]
are \( \text{GL}_2 \)-equivariant isomorphisms.

Of course, one can prove Proposition 2 directly. It is easy to see that the
mappings are $\text{GL}_2$-equivariant. Moreover, after counting dimensions in any
degree, it suffices to prove that the first mapping is injective. But, if $f$ and $g$
are homogeneous, $f$ of degree $l$, say, then
\[
\partial_u g - \partial_v f = 0 = uf + vg
\]
implies by Euler's relation
\[
0 = \partial_u (uf + vg) = f + u\partial_u f + v\partial_v g = f + (u\partial_u f + v\partial_v f) = (l + 1)f,
\]
hence $f = 0$, and also $g = 0$.

There is still another reason for this form of Clebsch–Gordan
isomorphism: Since $u, v$ form a regular sequence in $\mathcal{O}_{V,0}$, there exists a finite
free resolution of the $\mathcal{O}_V$-module $m_{V,0}$ by the Koszul complex which might
be written as
\[
0 \to \Omega^2_V \xrightarrow{E} \Omega^1_V \xrightarrow{I} m_{V,0} \to 0,
\]
where $E$ and $I$ are defined by contraction with the $\text{GL}_2$-invariant Euler
derivation $u\partial_u + v\partial_v$, such that
\[
E(du \wedge dv) = h(udv - vdu)
\]
is multiplication by the form $udv - vdu$ (which transforms under $\text{GL}_2$ by
multiplication of the determinant) and $I$ is given as above by integration:
\[
I(du + g dv) = uf + vg.
\]
Hence, (20) is a $\text{GL}_2$-equivariant exact sequence of $\mathcal{O}_V$-modules. Moreover,
the corresponding graded sequence splits as a sequence of $\text{Gr} \mathcal{O}_{V,0}$-modules,
since for homogeneous $h$ of degree $l$ we have
\[
D \circ E(h du \wedge dv) = D(hu dv - hv du)
= (\partial_u(hu) + \partial_v(hv)) du \wedge dv
= (l + 2) h du \wedge dv
\]
and
\[
(I \circ d)(h) = I((\partial_u h) du + (\partial_v h) dv)
= u\partial_u h + v\partial_v h
= lh.
\]

3. Reformulation of Pinkham's description of $T^1_Y$
For any $f \in H^0(V, \mathcal{O}_V)$ there exists a canonical cup-product mapping
\[
H^1(U, \mathcal{O}_V) \cup \xrightarrow{fr} H^1(U, \mathcal{O}_V).
\]
which can be defined by
\begin{equation}
[f_{12}] \cup f = [f_{12}f].
\end{equation}
If \( f \) is a homogeneous polynomial of degree \( d \), then
\begin{equation}
(\cup f): H^1(\mathcal{O}_U, -(l+2)) \rightarrow H^1(\mathcal{O}_U, -(l-d+2)),
\end{equation}
and the composition
\begin{equation}
S^*_{l, x} \rightarrow H^1(\mathcal{O}_U, -(l+2)) \rightarrow H^1(\mathcal{O}_U, -(l-d+2)) \rightarrow S^*_{l-d, x} \rightarrow 1
\end{equation}
is again denoted by \( \cup f \). Obviously
\begin{equation}
\partial_{jk} \cup u^r v^s = \partial_{j-r, k-s}, \quad j \geq r, \ k \geq s,
\end{equation}
and zero otherwise. By the cup-product one can define a new mapping
\begin{equation}
\cup f: H^1(U, \Theta_Y) \rightarrow H^1(U, \mathcal{O}_Y),
\end{equation}
setting
\begin{equation}
(\xi \otimes \partial_u + \eta \otimes \partial_v) \cup f = \xi \cup (\partial_u f) + \eta \cup (\partial_v f).
\end{equation}
Again, if \( f \in S_d \), the cup-product respects the grading. We denote the composition
\begin{equation}
S^*_{-2} \cup \rightarrow H^1(U, \Theta_Y) \rightarrow \cup f H^1(U, \mathcal{O}_Y) \rightarrow S^*_{-1}
\end{equation}
by \( \cup f \), and the corresponding composition with \( I^* \) by
\begin{equation}
\bigcup_l f: S^*_{+, x} \rightarrow \bigoplus_{l=1}^\infty S^*_{l, x} \rightarrow S^*_{-1}.
\end{equation}
It is simply checked that
\begin{equation}
\partial_{jk} \cup u^r v^s = [(k+1) r - (j+1) s] \partial_{j-r+1, k-s+1},
\end{equation}
\begin{equation}
\partial_{jk} \cup u^r v^s = (r+s) \partial_{j-r, k-s}.
\end{equation}

Now let \( G \subset \text{GL}_2 \) be any finite subgroup. Via the embedding in \( \text{GL}_2 \), \( G \) acts on every \( \text{GL}_2 \)-module \( M \). We denote by \( M^G \) the absolute invariants:
\begin{equation}
M^G = \{ m \in M: g(m) = m \text{ for all } g \in G \}.
\end{equation}
By the definition of \( M^G \),
\begin{equation}
M^G = (M^G)^G = \{ m \in M: g(m) = \Delta(g)^k m \text{ for all } g \in G \}.
\end{equation}
In particular, the invariant algebra \( S^G \) is finitely generated by a (minimal) system of homogeneous polynomials \( P_1, \ldots, P_e \), and it is easily seen that
\begin{equation}
\bigcup P_e: H^1(U, \Theta_Y)^G \rightarrow H^1(U, \mathcal{O}_Y)^G.
\end{equation}
Pinkham proved in [7] that the vector space $T^1_X$ of first order infinitesimal deformations of the singularity of $X = V/G$ at the origin is equal to the intersection of the kernels of these mappings. Therefore we get

**Theorem 1.** Let $G \subset \text{GL}_2$ be a finite subgroup, and let $P_1, \ldots, P_e$ be a minimal set of generators for the invariant algebra $S^G$. Then the vector space $T^1_X$ of infinitesimal deformations of the quotient singularity $X = V/G$ is isomorphic to the kernel of the C-linear mapping

$$ \alpha^*: (S^*_{x-2})^G \oplus (S^*_{x+1})^G \to \bigoplus_{\varepsilon=1}^e (S^*_{x-1})^G $$

which is defined by

$$ \alpha^*(\partial_1, \partial_2) = (\delta_1, \ldots, \delta_e), \quad \delta_\varepsilon = (\partial_1 \cup P_\varepsilon) + (\partial_2 \cup P_\varepsilon). $$

Since it is very easy to compute bases for all invariant spaces $S^G_t, t^*,$ (see e.g. [9], [5]), the determination of the infinitesimal deformations of fixed degree is reduced to the solution of a concrete system of linear equations. So, if one knows an a priori bound for these degrees, Theorem 1 gives one an effective way to compute $T^1_X$ for a given group. We have done these computations for the binary polyhedral groups $T, O$ and $I$, where we found the more or less expected results. However, such computations are much simpler, if one dualizes Theorem 1, as was remarked by H. Knörrer.

4. Dualization of the main result

For $f \in H^0(V, \Theta_V)$, the dual mapping

$$ H^0(V, \Omega^2_V) \cong H^1(U, \Theta_V)^* \to H^1(U, \Theta_V)^* \cong H^0(V, \Omega^2_V) $$

is just multiplication by $f$, and

$$ H^0(V, \Omega^2_V) \cong H^1(U, \Theta_V)^* \to H^1(U, \Theta_V)^* \cong H^0(V, \Omega^1_V \otimes \Omega^2_V) $$

(the middle map in both lines being $(\cup f)^*$) is given by

$$ \omega \mapsto df \otimes \omega, $$

$\omega \in H^0(V, \Omega^2_V), df = (\partial_u f) du + (\partial_v f) dv$. So, dualizing Pinkham's description, we obtain

**Theorem 2.** Let $G \subset \text{GL}_2$ be a finite subgroup, and let $P_1, \ldots, P_e$ be a (minimal) set of homogeneous generators of the invariant algebra $S^G$. Then, the dual $(T^1_X)^*$ is canonically isomorphic to the cokernel of the $S^G$-module homomorphism

$$ \bigoplus_{\varepsilon=1}^e H^0(V, \Omega^2_V)^G \to H^0(V, \Omega^1_V \otimes \Omega^2_V)^G $$
given by

\[ (\omega_1, \ldots, \omega_e) \mapsto \sum_{\epsilon=1}^{e} dP_\epsilon \otimes \omega_\epsilon. \]

By Hartog's Theorem, \( H^0(U, \mathcal{F}) \cong H^0(V, \mathcal{F}) \) for all free \( \mathcal{C}_\nu \)-modules \( \mathcal{F} \)
of finite rank. Therefore, if we denote \( V/G \) by \( X \) and the regular part \( U/G \) of \( X \) by \( X' \), we get

\[ H^0(V, \Omega^2_{\mathcal{F}})^G \cong H^0(X', \Omega^2_{\mathcal{F}}) \cong H^1(X', \mathcal{C}_X)^* \]

and

\[ H^0(V, \Omega^1_{\mathcal{F}} \otimes \Omega^1_{\mathcal{F}})^G \cong H^0(X', \Omega^1_{X} \otimes \Omega^1_{X}) \cong H^1(X', \mathcal{C}_X)^*, \]

such that Theorem 2 also could have been proven directly by dualizing Schlessinger's exact sequence for \( T^1_X \) (see [1]).

Combining Propositions 1 and 2, we get the following dual version of Theorem 1:

**Proposition 3.** Let \( G \subset GL_2 \) be a finite subgroup, and let \( P_1, \ldots, P_e \) be a minimal set of homogeneous generators of the invariant algebra \( S^G \), of degree \( l_1, \ldots, l_e \), say. Then the dual vector space \((T^1_X)^*\) is canonically isomorphic to the cokernel of the \( C \)-linear mapping

\[ \alpha: \bigoplus_{\epsilon=1}^{e} S^G_{\epsilon} \rightarrow S^G_{-2} \oplus S^G_{+,X} \]

where

\[ \alpha(\omega_1, \ldots, \omega_e) = (J(\omega_1, \ldots, \omega_e), K(\omega_1, \ldots, \omega_e)), \]

\[ J(\omega_1, \ldots, \omega_e) = \sum_{\epsilon=1}^{e} J(P_\epsilon, \omega_\epsilon), \quad J(P, \omega) = \partial_\omega P \cdot \partial_\nu + \partial_\nu P \cdot \partial_\omega, \]

\[ K(\omega_1, \ldots, \omega_e) = \sum_{\epsilon=1}^{e} l_\epsilon P_\epsilon \omega_\epsilon. \]

In order to obtain concrete bases for \((T^1_X)^*\) or at least dimension formulas, it is necessary to analyze the mappings \( J \) and \( K \) in Proposition 3 a little further. Notice that \( K \) is a \( S^G \)-module homomorphism, but \( J \) is certainly not. However, the following is true:

**Theorem 3.** Under the assumptions of Theorem 2 the set

\[ \mathcal{J} = \{ h \in S^G_{\epsilon,2} : h = J(\omega_1, \ldots, \omega_e), K(\omega_1, \ldots, \omega_e) = 0 \} \]

is a \( S^G \)-submodule of \( S^G_{\epsilon,2} \) which contains all elements

\[ J(f, g)\omega, \quad f, g \in S^G, \quad \omega \in S^G_{\epsilon}. \]

\((T^1_X)^*\) fits as \( S^G \)-module into an exact sequence

\[ 0 \rightarrow S^G_{\epsilon,2}/\mathcal{J} \rightarrow (T^1_X)^* \rightarrow (S^G_{+,X}/\text{im } K) \rightarrow 0. \]
Proof. Since $\mathcal{J} = \text{im}(J|\ker K)$, the exactness of the $S^G$-sequence (29) follows from the first assertion. The mapping $K$ may be, as $S^G$-module homomorphism, identified with the composition

$$
\bigoplus_{\epsilon = 1}^e H^0(V, \Omega^2_V)^G \xrightarrow{\mu} H^0(V, \Omega^1_V \otimes \Omega^1_V)^G \xrightarrow{E \otimes \text{id}} H^0(V, \Omega^2_V)^G
$$

where $\mu$ is the mapping in Theorem 2 and $I$ is defined in Section 2. So, for $\omega = (\omega_1, \ldots, \omega_e)$ with $K(\omega) = 0$, there exists a unique $\eta \in H^0(V, \Omega^2_V \otimes \Omega^2_V)$ with $(E \otimes \text{id})(\eta) = \mu(\omega)$. Since the mapping $J$ is the composition of $\mu$ with a left inverse to $E \otimes \text{id}$, it follows that

$$
J(\omega) = \eta.
$$

The first claim is hence implied by the fact that $E \otimes \text{id}$ is $S^G$-linear.

For the remaining part it is enough to show that $J(P_\sigma, P_\nu) \omega \in \mathcal{J}$ for all $\sigma, \nu$ and all homogeneous $\omega \in S^G_\omega$. Take $\omega_\phi = -l_\nu P_\sigma \omega$, $\omega_\nu = l_\sigma P_\phi \omega$, $\phi < \nu$, $\omega_\sigma = 0$, $\sigma \neq \phi, \nu$, $\omega = (\omega_1, \ldots, \omega_e)$. Then we have

$$
\mu(\omega) = (-l_\nu P_\sigma dP + l_\sigma P_\phi dP) \omega
= \left[ -(u \partial_u P_\nu + v \partial_v P_\nu)(\partial_u P_\sigma du + \partial_v P_\nu dv)
+ (u \partial_u P_\sigma + v \partial_v P_\sigma)(\partial_u P_\nu du + \partial_v P_\nu dv) \right] \omega
= [(\partial_u P_\nu)(\partial_u P_\sigma) - (\partial_u P_\sigma)(\partial_u P_\nu)](v du - u dv) \omega
= J(P_\nu, P_\sigma)(v du - u dv) \omega = (E \otimes \text{id})(J(P_\nu, P_\sigma) \omega),
$$

such that, up to a non-trivial constant, $J(\omega)$ is equal to

$$
J(P_\nu, P_\sigma) \cdot \omega.
$$

In Sections 6 and 7 we shall apply this result to the problem of the determination of $\dim T^1_\chi$ for all groups $G \subset \text{GL}_2$. The special case of rational double points is treated in the following section.

5. $(T^1_\chi)^*$ and $T^1_\chi$ for rational double points

Suppose now that $G \subset \text{SL}_2$ such that $S^G_\chi = S^G_{\chi_2} = S^G$. Moreover, since $1 \in S^G_\chi$, we have $P_\epsilon \in \text{im} K$ for all $\epsilon = 1, \ldots, e$, and by the same reason the ideal $\mathcal{J} \subset S^G = S^G_{\chi_2}$ contains all elements $J(P_\nu, P_\mu)$. On the other hand, each element of $\mathcal{J}$ is of the form

$$
\sum_{\epsilon = 1}^e J(P_\epsilon, Q_\epsilon), \quad Q_\epsilon \in S^G,
$$

and therefore it is contained in the ideal generated by the elements $J(P_\nu, P_\mu)$. So we get
THEOREM 4. For finite $G \subset \mathrm{SL}_2$, the $S^G$-module $(T^G_x)^*$ is canonically isomorphic to $S^G/\mathcal{J}$, where $\mathcal{J}$ is the ideal generated by the Jacobians $J(P_v, P_u)$ of a minimal set of generators $P_1, \ldots, P_e$.

Of course, Theorem 4 is only remarkable by the fact that we proved it without any special knowledge of the invariant theory of the binary polyhedral groups. Indeed, using Felix Klein's results ([6]), the proof of Theorem 4 is a simple exercise: For a finite group $G \subset \mathrm{SL}_2$ the invariant ring $S^G$ is generated by three homogeneous polynomials $w_1, w_2, w_3$ satisfying only one generating polynomial relation

$$R(w_1, w_2, w_3) = 0.$$ 

Hence, $S^G \cong C[w_1, w_2, w_3]/\text{ideal}$ generated by $R$. For suitably chosen $w_1, w_2, w_3$, there exists a constant $C \neq 0$ such that

$$J(w_\varepsilon, w_{\varepsilon+1}) = C \frac{\partial R}{\partial w_{\varepsilon+2}}, \quad \varepsilon \in \mathbb{Z}_3.$$  

(We prove this fact in Lemma 2 below). Hence,

$$S^G/\mathcal{J} \cong C[w_1, w_2, w_3]/\left(R, \frac{\partial R}{\partial w_1}, \frac{\partial R}{\partial w_2}, \frac{\partial R}{\partial w_3}\right),$$

and this is the description of $(T^G_x)^*$ for $X = \{(w_1, w_2, w_3) \in C^3 : R(w_1, w_2, w_3) = 0\} \cong C^2/G$ which we mentioned in the introduction.

LEMMA 2. For $G \subset \mathrm{SL}_2$ there exist generators $w_1, w_2, w_3$ of $S^G$ with a generating relation $R$ such that (30) holds.

Proof. For a cyclic group of order $n = r+1 \geq 2$, generated by the element

$$\begin{bmatrix} \zeta_n & 0 \\ 0 & \zeta_n^{-1} \end{bmatrix},$$

$\zeta_n$ a $n$th primitive root of unity, we have obviously generators $u^n, v^n$ and $uv$, satisfying $(u^n)(v^n) = (uv)^n$. By putting

$$w_1 = uv, \quad w_2 = \frac{1}{2}(u^n + v^n), \quad w_3 = \frac{1}{2}(u^n - v^n),$$

we get new generators satisfying the relation $R = 0$, where

$$R(w_1, w_2, w_3) = w_1^n - w_2^2 + w_3^2.$$ 

A simple calculation shows that

$$J(w_1, w_2) = \frac{n}{2}(v^n - u^n) = \frac{n}{2} \frac{\partial R}{\partial w_3}. $$
\[ J(w_2, w_3) = -\frac{n^2}{2} (uv)^{n-1} = \frac{n}{2} \frac{\partial R}{\partial w_1}, \]

\[ J(w_3, w_1) = \frac{n}{2} (u^n + v^n) = \frac{n}{2} \frac{\partial R}{\partial w_2}. \]

For the binary dihedral groups \( D_n \) of order \( 4n \), \( n = r - 2 \geq 2 \), and the binary tetrahedral, octahedral and icosahedral group \( T \), \( O \) and \( I \) respectively, there exist generators \( w_1, w_2, w_3 \) with the following degrees:

<table>
<thead>
<tr>
<th></th>
<th>deg ( w_1 )</th>
<th>deg ( w_2 )</th>
<th>deg ( w_3 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( D_n )</td>
<td>4</td>
<td>2n</td>
<td>2n+2</td>
</tr>
<tr>
<td>( T )</td>
<td>6</td>
<td>8</td>
<td>12</td>
</tr>
<tr>
<td>( O )</td>
<td>8</td>
<td>12</td>
<td>18</td>
</tr>
<tr>
<td>( I )</td>
<td>12</td>
<td>20</td>
<td>30</td>
</tr>
</tbody>
</table>

which satisfy a relation of the type

\[ R(w_1, w_2, w_3) = w_3^2 + g(w_1, w_2) = 0. \]

Since \( G = SL_2 \), \( J(w_1, w_2) \in S^G \), and since obviously in all cases \( \text{deg} J(w_1, w_2) = \text{deg} w_3 \), there exists a constant \( C \) such that

\[ J(w_1, w_2) = 2Cw_3 = C \frac{\partial R}{\partial w_3}. \]  

(31)

(In fact, Klein found \( w_1, w_2, w_3 \) by constructing the invariant \( w_1 \) of lowest degree and by putting

\[ w_2 = \text{Hesse} (w_1) = \det \begin{bmatrix} \partial^2 w_1 & \partial_u \partial_{v} w_1 \\ \partial_u \partial_{u} w_1 & \partial^2 w_1 \end{bmatrix}, \quad w_3 = J(w_1, w_2). \]

Now, for all \( \varepsilon \),

\[ 0 = J(R(w_1, w_2, w_3), w_3) \]

\[ = \det \left[ \begin{array}{cc} \sum_{\mu} \frac{\partial R}{\partial w_{\mu}} \frac{\partial w_{\mu}}{\partial u} & \sum_{\mu} \frac{\partial R}{\partial w_{\mu}} \frac{\partial w_{\mu}}{\partial v} \\ \frac{\partial w_{\varepsilon}}{\partial u} & \frac{\partial w_{\varepsilon}}{\partial v} \end{array} \right] = \sum_{\mu} \frac{\partial R}{\partial w_{\mu}} J(w_{\mu}, w_{\varepsilon}) \]

which implies (30) using (31).

\[ \square \]

Another advantage of our description of \( (T^1_X)^* \) is the possibility to calculate a basis for \( T^1_X \) itself. Recall that there exist \( GL_2 \)-isomorphisms

\[ S_l \rightarrow S^*_{l, X} \]
sending $u^j v^k$ to $(-1)^k \partial_u^j \partial_v^k$, $j + k = l$. Hence, for a binary polyhedral group $G \subseteq \text{SL}_2$, these mappings induce isomorphisms
\[ \gamma_l : S^G_l \rightarrow (S^G_l)^G. \]

For a polynomial $Q \in S^G_l$ we denote the corresponding differential operator $\gamma_l(Q)$ by $Q(\partial)$. $\gamma_l$ gives rise to a non-degenerate bilinear form $(\ , \ )$ on $S^G_l$ by
\[ (Q_1, Q_2) := \langle Q_1, \gamma_l(Q_2) \rangle = Q_2(\partial)Q_1. \]

If now $\mathcal{J}_l = \mathcal{J} \cap S^G_l$, there exists an orthogonal complement of $\mathcal{J}_l$ in $S^G_l$ with respect to this bilinear form which we call $\tilde{\mathcal{J}}_l$:
\[ \mathcal{J}_l \oplus \tilde{\mathcal{J}}_l = S^G_l. \]

Then we get at once

**Corollary 1.** Let $Q_1, \ldots, Q_r$ be a homogeneous basis of the finite dimensional vector space $\bigoplus_{l=0}^\infty \tilde{\mathcal{J}}_l \subset \bigoplus_{l=0}^\infty S^G_l$. Then, a basis of $T^1_\mathcal{J}$ in $H^1(U, \Theta_{\mathcal{J}})$ is given by the images of the operators $Q_1(\partial), \ldots, Q_r(\partial)$ under the mapping $D_\ast$ of Proposition 1.

To get a more precise result, let us first analyze the case of a cyclic group $G$ of order $n = r + 1 \geq 2$ in $\text{SL}_2$. The vector space $S^G_l$ is generated by the elements
\[ u^j v^k, \quad j - k \equiv 0 \mod n, \quad j + k = l, \]
and generators for the ideal $\mathcal{J}$ are $u^n$, $v^n$, $(uv)^{n-1}$. Hence, for an element $u^j v^k \in S^G_l$:
(a) $j \neq k \Rightarrow u^j v^k \in \mathcal{J}$, since $j = k + \lambda n$, $\lambda \in \mathbb{Z} \setminus \{0\}$;
(b) $j = k \geq n - 1 \Rightarrow u^j v^k \in \mathcal{J}$;
(c) $j = k < n - 1 \Rightarrow u^j v^k \notin \mathcal{J}$.

So, we have
\[ \mathcal{J}_l = S^G_l \quad \text{for } l \geq 2n - 2 \text{ or odd } l < 2n - 2, \]
\[ \mathcal{J}_l \oplus \langle u^j v^k \rangle = S^G_l \quad \text{for } l = 2\lambda \leq 2n - 4. \]
But for $u^j v^k \in \mathcal{J}_l$, $l = 2\lambda \leq 2n - 4$, we have $j < \lambda$ or $k < \lambda$ such that
\[ \partial_u^j \partial_v^k (u^j v^k) = 0. \]
Therefore, (32) is the orthogonal decomposition, and the Corollary 1 applies to the $r = n - 1$ polynomials
\[ Q_1 = 1, \quad Q_2 = uv, \ldots, Q_r = (uv)^{r-1}, \]
i.e.,
\[ w_1^0, \quad w_1^1, \ldots, w_1^{n-2}. \]
In the other cases, we use the same generators as in Lemma 2 such that
a basis of $S^G/I$ can be represented by elements of type $w_1^j w_2^k \in S^G$, only. These elements occur in different degrees such that again

$$\mathfrak{I}_1 = S^G \quad \text{or} \quad \mathfrak{I}_1 \oplus \mathfrak{I}_1 = S^G,$$

where $\mathfrak{I}_1$ is generated by one element of type $w_1^j w_2^k$, $j \deg w_1 + k \deg w_2 = 1$. By using the explicit form of the generators $w_1$, $w_2$, $w_3$ and the relation $R$, the reader may check himself that indeed $\mathfrak{I}_1 = \mathcal{T}_1$, i.e., that the elements $w_1^j w_2^k$ which are not in $\mathfrak{I}$ form a basis $Q_1, \ldots, Q_r$ as in the Corollary 1.

6. Some remarks on the modules $S^G_{+^e, x}/\ker K$ and $S^G_{x^2}/\mathfrak{I}$

From now on we assume $G \subset G L_2$ to be small, i.e., $G$ contains no pseudoreflections, and that $N = G \cap S L_2$ is properly contained in $G$. Then, as is well known, the minimal number $e$ of generators $P_1, \ldots, P_e$ of $S^G$ is equal to the embedding dimension $\text{emb} \, X$ of the quotient $X = V/G$ and $e \geq 4$.

Henceforth, $X$ cannot be realized as a hypersurface in $C^3$. In fact, $\binom{e-1}{2}$ equations are needed to describe $X$ as a subspace of $C^e$ such that $X$ is never a complete intersection which makes the determination of $T^X_1$ a difficult task.

From the complete knowledge of Betti numbers ([13]) one can deduce, moreover, that the dualizing module $\omega_X$ is minimally generated at the singularity $x$ by $e - 2$ elements, i.e.,

$$\dim_c \omega_{X,x}/m_{X,x} \omega_{X,x} = e - 2.$$

Returning to Theorem 3 again we see that in this case $1 \notin S^G_2$ such that

$$S^G_{+^e, x} = S^G_x = H^0(X', \Omega^2_X) = H^0(X, \omega_X),$$

since $\omega_X$ is the reflexive hull of the sheaf $\Omega^2_X$. But, by definition, $\ker K$ equals the $S^G$-submodule of $H^0(X, \omega_X)$ generated by $P_1, \ldots, P_e$. After localization at $x$ we conclude that

$$\dim_c S^G_{+^e, x}/\ker K = e - 2.$$

It is clear, how one can get concrete infinitesimal deformations in $H^1(U, \Theta_Y)$ from a generating set $\tilde{\omega}_1, \ldots, \tilde{\omega}_{e-2}$ of homogeneous elements in $S^G_x$ by duality.

So, we concentrate on the module $S^G_x/\mathfrak{I}$. Denote by $\mathfrak{R}$ the relation module of $S^G_x$, i.e., the kernel of the epimorphism

$$\bigoplus_{j=1}^{e-2} S^G \to S^G_x$$

given by

$$(g_1, \ldots, g_{e-2}) \mapsto \sum_{j=1}^{e-2} g_j \tilde{\omega}_j,$$
where \{\tilde{\omega}_1, \ldots, \tilde{\omega}_{e-2}\} denotes a minimal set of generators for \(S^G_\chi\). We grade \(\mathcal{R}\) by

\[
\deg(g_1, \ldots, g_{e-2}) = l \iff \deg g_j + \deg \tilde{\omega}_j = l, \ j = 1, \ldots, e - 2.
\]

We have a grading on \(\ker K\), too: If

\[
(\omega_1, \ldots, \omega_e) \in \ker K \subset \bigoplus_{\varepsilon = 1}^e S^G_\varepsilon,
\]

then

\[
\deg(\omega_1, \ldots, \omega_e) = l \iff \deg \omega_\varepsilon + l_\varepsilon = l, \ \varepsilon = 1, \ldots, e.
\]

(Recall that \(l_\varepsilon = \deg P_\varepsilon\)). Finally, we denote by \(\mathcal{S}\) the graded submodule of trivial relations \((\omega_1, \ldots, \omega_e)\) with \(\omega_\varepsilon = l_\mu P_\mu \omega, \ \omega_\mu = -l_\nu P_\nu \omega, \ \mu \neq \nu\) fixed, \(\omega_\sigma = 0, \ \sigma \neq \mu, \nu\). Then, for \((g_1, \ldots, g_{e-2}) \in \mathcal{R}\), all \(g_j\) are in \(S^G_+\), since \(\tilde{\omega}_1, \ldots, \tilde{\omega}_{e-2}\) form a minimal set of generators. Hence,

\[
g_j = \sum_{\varepsilon = 1}^e l_\varepsilon P_\varepsilon R_{j\varepsilon}
\]

for some \(R_{j\varepsilon} \in S^G_\varepsilon\). Because of

\[
0 = \sum_{j=1}^{e-2} g_j \tilde{\omega}_j = \sum_{\varepsilon = 1}^e l_\varepsilon P_\varepsilon (\sum_{j=1}^{e-2} R_{j\varepsilon} \tilde{\omega}_j),
\]

we see that

\[
\omega = (\omega_1, \ldots, \omega_e) \in \ker K,
\]

if \(\omega_\varepsilon = \sum_{j=1}^{e-2} R_{j\varepsilon} \tilde{\omega}_j\). Of course, \(\omega\) is not well defined, but it is easily seen that it is unique modulo \(\mathcal{R}\). On the other hand, it is clear that each relation

\[
\sum_{\varepsilon = 1}^e l_\varepsilon P_\varepsilon \omega_\varepsilon = 0
\]

can be transformed into a relation

\[
\sum_{j=1}^{e-2} g_j \tilde{\omega}_j = 0
\]

by writing

\[
\omega_\varepsilon = \sum_{j=1}^{e-2} Q_{j\varepsilon} \tilde{\omega}_j.
\]

By this procedure we have constructed a surjective \(S^G\)-homomorphism:

\[
\mathcal{R} \twoheadrightarrow \ker K/\mathcal{S}.
\]

Since, in the proof of Theorem 3, we have shown that the image of \(J|\mathcal{S}\) is the
$S^G$-module generated by the elements $J(P_\mu, P_\nu) \bar{\omega}_j$, we finally get the following result:

**Proposition 4.** The submodule $\mathcal{J} \subset S_{x^2}^G$ can be written in the form $\mathcal{J} = \mathcal{J}' + \mathcal{J}''$, where $\mathcal{J}'$ is generated by the elements $J(P_\mu, P_\nu) \bar{\omega}_j$, and $\mathcal{J}''$ is generated by the elements

\[
\sum_{\epsilon=1}^{e} R_{j\epsilon}^\tau J(P_\epsilon, \bar{\omega}_j), \quad j = 1, \ldots, e - 2, \quad \tau = 1, \ldots, t,
\]

coming from a generating system of relations

\[
\sum_{j=1}^{e - 2} \left( \sum_{\epsilon=1}^{e} l_\epsilon P_\epsilon R_{j\epsilon}^\tau \right) \bar{\omega}_j = 0, \quad \tau = 1, \ldots, t.
\]

Of course, we should mention that $t$ is of order $e^3$, as is the number of generators for $\mathcal{J}'$ such that Proposition 4 gives no effective way for computing $S_{x^2}^G/\mathcal{J}$. However, we will see in the next section that, in concrete cases, we need much less relations.

It is interesting to note that one can drop the number of relations drastically, if one studies ker $K$ before taking invariants. To be more precise, we define an $S$-module homomorphism $\tilde{K}$:

\[ \tilde{K}: \bigoplus_{\epsilon=1}^{e} S \to S \]

by

\[ \tilde{K}(\omega_1, \ldots, \omega_e) = \sum_{\epsilon=1}^{e} l_\epsilon P_\epsilon \omega_\epsilon, \]

whose image is the ideal in $S$ generated by the invariants $P_1, \ldots, P_e$. So, $\tilde{K}$ is the beginning of a projective resolution

\[ \ldots \to \bigoplus_{\epsilon=1}^{e} S \tilde{K} \to S \to S/\text{im} \tilde{K} \to 0 \]

of the structure sheaf of the zero-dimensional fibre of the canonical cover $V \to V/G \cong X$ at the origin of $V$. Since this fibre is of codimension $2$, im $\tilde{K}$ can be written by a result of Hilbert as the maximal minors of a $(e - 1)$ by $e$ matrix. For instance, we have for rational double points the matrix

\[ \begin{bmatrix} v & \partial_v w_1 & \partial_v w_2 \\ -u & \partial_u w_1 & \partial_u w_2 \end{bmatrix}. \]

From the Eagon–Northcott complex it follows that ker $\tilde{K}$ is free of rank $e - 1$ (each row of the matrix giving a relation). Of course,

\[ \ker K = (\ker \tilde{K}) \cap (S_{x^2})^e \quad \text{and} \quad \im(J|\ker K) = [\im(J|\ker \tilde{K})] \cap S_{x^2}^G, \]
where $\bar{J}$ is given by

$$\bar{J}(\omega_1, \ldots, \omega_e) = \sum_{\varepsilon=1}^e J(P_\varepsilon, \omega_\varepsilon),$$

since $\bar{K}$ and $\bar{J}$ are $G$-equivariant mappings.

We shall apply this method to the case of cyclic quotients in the rest of this section. The method works similarly for the dihedral singularities. For the exceptional cases, however, we did not make any attempt to find the matrices which describe $\text{im}\bar{K}$. (To our knowledge, they are not in the literature). Indeed, the most effective way for computing $(T_1^n)^G$ in these cases seems to be a compromise between taking all invariants and taking no invariants before computing $\ker K$, namely to take invariants under $N = G \cap \text{SL}_2$. We come back to this idea in the next section.

To apply our second method to cyclic quotient singularities we have to collect some facts and notations: Each cyclic quotient of order $n$ is determined by $n$ and another natural number $q$ such that $0 < q < n$ and $\gcd(n, q) = 1$; there exists a uniquely determined linear action of $\mathbb{Z}_n = \mathbb{Z}/n\mathbb{Z}$ on $V$ such that the action of a generator of $\mathbb{Z}_n$ on $S = C[u, v]$ is given by

$$u \mapsto \zeta_n^j u, \quad v \mapsto \zeta_n^q v.$$

Hence, the invariant algebra $S^{\mathbb{Z}_n}$ under this action is generated by all monomials $u^j v^k$ with $j + qk \equiv 0 \mod n$. A minimal set of generators can be found in the following way (see e.g. [8] for the following or any text on toroidal embeddings): Develop first the rational number $n/(n-q)$ into a Hirzebruch–Jung continued fraction:

$$\frac{n}{n-q} = \frac{1}{a_2 - \frac{1}{a_3 - \frac{1}{a_4 - \ldots}}}, \quad a_\varepsilon \geq 2,$$

and define

$$j_1 = n, \quad j_2 = n-q, \ldots, j_{\varepsilon+1} = a_{\varepsilon} j_\varepsilon - j_{\varepsilon-1}, \ldots$$

$$k_1 = 0, \quad k_2 = 1, \ldots, k_{\varepsilon+1} = a_\varepsilon k_\varepsilon - k_{\varepsilon-1}, \ldots$$

($j_\varepsilon$ and $k_\varepsilon$ are called $i_\varepsilon$ and $j_\varepsilon$, resp., in [8]). Then

$$P_\varepsilon = u^{j_\varepsilon} v^{k_\varepsilon}, \quad \varepsilon = 1, \ldots, e,$$

is a minimal set of generators of the invariant algebra. Since the sequence $j_\varepsilon$ is strictly decreasing and $k_\varepsilon$ is strictly increasing, we can write the ideal in $S$ generated by $P_1, \ldots, P_e$ as the maximal minors of the matrix
\[
\begin{bmatrix}
    u^{j_1-j_2} & v^{k_2-k_1} & 0 & 0 \\
    0 & u^{j_2-j_3} & v^{k_3-k_2} & 0 \\
    \cdots \cdots \cdots & \cdots & \cdots & \cdots \\
    0 & 0 & \cdots & u^{j_{e-1}-j_e} v^{k_e-k_{e-1}}
\end{bmatrix}.
\]

(Notice that \(j_e = 0\) and \(k_e = n\)). Hence, \(\ker \tilde{K}\) is generated by the \(e-1\) relations
\[
r_e: u^{j_e-j_{e+1}} P_{e+1} - v^{k_{e+1}-k_e} P_e = 0, \quad e = 1, \ldots, e-1,
\]
and \(\text{im}(\tilde{J}|\ker \tilde{K})\) is generated by the elements
\[
\frac{1}{l_{e+1}} J(u^{j_{e+1}} v^{k_{e+1}}, u^{j_e-j_{e+1}}) = \frac{1}{l_e} J(u^{j_e} v^{k_e}, v^{k_{e+1}-k_e})
\]
\[
= \left[ \frac{1}{l_{e+1}} k_{e+1} (j_e-j_{e+1}) + \frac{1}{l_e} j_e (k_{e+1}-k_e) \right] u^{j_{e-1}} v^{k_{e+1}-1}.
\]

Since the generator of \(\mathbb{Z}_n\) acts on \(S_x^2\) by
\[
u^j v^k \mapsto \zeta_n^{j+k}(\zeta_n^1 + q)^2 u^j v^k,
\]
the invariant \(S^\mathbb{Z}_n\)-module \(S_x^\mathbb{Z}_n^2\) is generated by all monomials
\[
u^j v^k \quad \text{with} \quad (j+2)+q(k+2) \equiv 0 \mod n.
\]
Hence, the dimension of \(S_x^\mathbb{Z}_n^2/\text{im}(\tilde{J}|\ker \tilde{K}) \cap S_x^\mathbb{Z}_n^2\) is equal to the cardinality of
\[
\{(j, k): j, k \geq 0, (j+2)+q(k+2) \equiv 0 \mod n, \forall e: j < j_e-1 \text{ or } k < k_{e+1}-1\},
\]
i.e., to the cardinality of
\[
\{(j, k): j \geq 2, k \geq 2, j+qk \equiv 0 \mod n, \forall e: j < j_e \text{ or } k \leq k_{e+1}\}.
\]
But this set consists for \(e \geq 4\) precisely of the pairs
\[
(\alpha \mu, j_{\mu}, k_{\mu}): \begin{cases}
\alpha \mu = 1, \ldots, a_\mu - 1, & \mu = 3, \ldots, e-2, \\
\alpha \mu = 2, \ldots, a_\mu - 1, & \mu = 2, e-1.
\end{cases}
\]
(Notice that \(k_2 = 1, j_{e-1} = 1\)). Hence,
\[
\dim(T_x^e)^* = (e-2) + \sum_{e-2} (a_e - 1) - 2
\]
\[
= (e-4) + \sum_{e-2} (a_e - 1).
\]
But, if
\[
\frac{n}{q} = b_1 - \frac{1}{b_2}, \quad b_2 \geq 2,
\]
\[
\frac{1}{b_3}, \quad \cdots, \quad \frac{1}{b_r}
\]
then the numbers \(-b_\varphi\) are the selfintersection numbers of the components of the exceptional set in a minimal resolution \(\tilde{X}\) of \(X = V/Z_n\), and
\[
\sum_{\varphi=1}^{r-1} (a_\varphi - 1) = \sum_{\varphi=1}^{r} (b_\varphi - 1)
\]
(see [8]) can be interpreted as the dimension of the base space of a versal deformation of \(\tilde{X}\), or, alternatively, as the dimension of the smooth component of the base space of a versal deformation of \(X\) consisting of simultaneously resolvable deformations (the Artin component).

In fact, one has for all quotient surface singularities of embedding dimension \(e \geq 4\) the equation
\[
\dim T_X^1 = (e - 4) + \sum_{\varphi=1}^{r} (b_\varphi - 1),
\]
where the numbers \(b_\varphi\) and the sum \(\sum_{\varphi=1}^{r} (b_\varphi - 1)\) have the same meaning as above (see [5], [1] and [2] and the tables at the end of the next section).

7. Some examples and complete results for the exceptional cases

We now illustrate how one can use the results of the previous sections to determine a basis for \((T_X^1)^*\) in the exceptional cases. In all these cases (with the exception of precisely one series which, however, can be handled in a similar way, see [5]), the group \(G\) is the product \(N \cdot Z_{2m} \subset GL_2\) of \(N = G \cap SL_2\) with the cyclic subgroup of order \(2m\) in the center of \(GL_2\) generated by \(\zeta_{2m}\cdot E\), \(\zeta_{2m}\) a \((2m)\)th primitive root of unity. Then, if \(x, y, z\) (instead of \(w_1, w_2, w_3\)) denote a system of generators of the algebra \(S^N\) as in Section 5, \(S_X^G\) is generated by all elements
\[
x^a y^b \quad \text{with} \quad a \deg x + b \deg y + 2l \equiv 0 \mod 2m
\]
and
\[
x^a y^b z \quad \text{with} \quad a \deg x + b \deg y + \deg z + 2l \equiv 0 \mod 2m.
\]

With respect to these bases the map \(J\) has a fairly simple description, since
\[
J(x^a y^b z^c, x^\delta y^\gamma z^\epsilon) = \det \begin{bmatrix}
a & b & c \\
\bar{a} & \bar{b} & \bar{c} \\
xJ(y, z) & yJ(z, x) & zJ(x, y)
\end{bmatrix} x^{a+\delta-1} y^{b+\gamma-1} z^{c+\epsilon-1}.
\]

Of course, formula (41) has the following interpretation: One has to develop the determinant, to multiply with the monomial on the utmost right side, to
delete terms with at least one negative exponent, and, finally, to replace \( z^2 \) or \( z^3 \) by \( x \) and \( y \) via the relation \( R \).

To have a concrete case let us concentrate on the series \( T_m = T \cdot Z_{2m}, \ m = 6(b-2)+1, \ b \geq 2. \) The corresponding singularity has a dual graph

\[
\begin{array}{cccccc}
-2 & -2 & \bullet & -b & -2 & -2 \\
\end{array}
\]

and embedding dimension \( e = b + 1 \). It is clear that the case \( b = 2 \) is a special one, namely the rational double point of type \( E_6 \). Unfortunately, the case \( b = 3 \) can also not be treated in a coherent manner together with all other cases (we shall see in a moment, why this is so). However, the case \( b = 4 \) shows all features of the rest of the series.

So, let us first determine for \( b = 4 \), i.e., for \( m = 13 \), the invariant algebra \( S^{T_m} \) (see also [9]). By (39) and (40) a basis is given in the first degrees by

\[
\begin{array}{cccccccc}
1 & 0 & 2 & 4 & 6 & 8 & \ldots \\
\hline
x^3 y & x^2 y^2 & x^2 y^3 & x^2 y^5 & x_3^2 & x^2 y^6 & x^2 y^7 & x^2 y^{10} \\
x^6 y & x^6 y^2 & x^6 y^3 & x^6 y^4 & x^6 y^7 & x^6 y^9 & x^2 y^{10} & x^6 y^{12} \\
\end{array}
\]

Here, \( \deg x = 6, \ \deg y = 8, \ \deg z = 12, \ z^2 + y^3 + x^4 = 0 \), and the \( e = 5 \) elements in boxes are algebra generators for \( S^{T_m} \).

Similarly, we get for \( S^{T_m}_x \):

\[
\begin{array}{cccccccc}
1 & 0 & 2 & 4 & 6 & 8 & \ldots \\
\hline
x^3 & y^3 & x^2 z & x^6 y & x^6 y^2 & x^6 y^3 & x^6 y^4 & x^6 y^7 \\
x^{10} y^2 & x^6 y^3 & x^2 y^6 & x^{14} y & x^{14} y^2 & x^{14} y^3 & x^{14} y^4 & x^{14} y^7 \\
x^{17} & x^{13} y^2 & x^9 y^6 & x^2 y^9 & x^{15} y & x^{15} y^2 & x^{15} y^3 & x^{15} y^6 \\
\end{array}
\]

where now the \( e-2 = 3 \) elements in boxes are generators for the \( S^{T_m}_x \)-module \( S^{T_m}_x \) contributing three dimensions to \( T^1_x \).

Finally, for \( S^{T_m}_{x^2} \), we find
Of course, elements in degree $2m$ cannot lie in \( \text{im}(J | \text{ker } K) \). We will show that 4 relations between the generators of \( S^{T^m} \) in \( S^T \) suffice to generate the module below, the broken line in the figure above. These relations are:

\[
\begin{align*}
(x^3 y) z - (xyz) x^2 &= 0, \\
(2y^5 z) x - (xyz) 2y^4 &= 0, \\
(3x^{11} z) y - (x^3 y) 3x^8 z &= 0, \\
(x^{11} z) x^2 - (x^{13}) z &= 0.
\end{align*}
\]

(42)

Simple calculations show that

\[
J(x^3 y, z) - J(xyz, x^2) = \begin{vmatrix} 3 & 1 & 0 \\ 0 & 0 & 1 \\ 4x^4 & 3y^3 & 2z^2 \end{vmatrix} - \begin{vmatrix} 1 & 1 & 1 \\ 2 & 0 & 0 \\ 4x^4 & 3x^3 & 2z^2 \end{vmatrix} x^2
\]

\[
= (-9y^3 + 4x^4 + 2(2z^2 - 3y^3)) x^2
\]

\[
= (4x^4 - 15y^3 - 4(y^3 + x^4)) x^2
\]

\[
= -19x^2 y^3,
\]

\[
J(y^5, z, x) - J(xyz, 2y^4) = 29y^7 + 58x^4 y^4,
\]

\[
J(x^{22}, z, y) - J(x^3 y, 3x^8 z) = -86x^{14} - 43x^{10} y^3,
\]

\[
J(x^{11} z, x^2) - J(x^{13}, z) = 45x^{10} y^2.
\]

Hence, \( x^2 y^3, y^7, x^{14} \) and \( x^{10} y^2 \) are in the \( S^T \)-module \( \text{im}(J | \text{ker } K) \), where now \( \text{ker } K \) denotes relations in \( S^T \). But then \( \text{im}(J | \text{ker } K) \) contains all elements in \( S_{x^2}^{T_1} \) with the possible exception of \( xy^2, x^8, y^6, x^6 z, x^{11} y \) and \( x^9 yz \). Hence,

\[
\dim T^1_x = 3 + 6 = 9 = 8 + 1,
\]

where \( 8 = \sum_{q=1}^{r} (b_q - 1) \) and \( 1 = e - 4 \). Since in (38) there always holds the
sign by a result of J. Wahl (see [1]), we have shown that
\[ \dim T^l \xi = 9 \quad \text{for} \quad X = C^2/T \cdot Z_{26}. \]
(It is also easily seen that the relations (42) are the only ones in low degrees, such that the dimension formula may be derived directly without Wahl's lower bound).

By the same procedure we see for general \( b \geq 4, \) \( m = 6(b - 2) + 1, \) that in degree \( 4m \) there are always precisely 3 and in degree \( 6m \) precisely 2 infinitesimal deformations coming from \( S^m_{x_2} \). In addition, we have all elements in degree \( 2m \) in \( S^m_{x_2} \) and all elements of degree \( 2m \) in \( S^m_x \) (the generators). This last number is equal to
\[ \dim S^m_{2m, x} + \dim S^m_{2m, x_2} = \dim S^m_{2m-2} + \dim S^m_{2m-4}. \]
It is easy to prove by invariant theory that
\[ \dim S^l + \dim S^l_{x_2} = 1, 0, 1, 2, 1, 2, 3, 2, 3, \ldots \]
for \( l = 0, 2, 4, 6, \ldots \). Hence, we get for \( l = 2m - 4 = 12(b - 2) - 2 \) that this number is equal to \( 2b - 4 \). Altogether we have
\[ \dim T^l \xi = (2b - 4) + 5 = 2b + 1 \]
\[ = (b + 4) + (b + 1 - 4) \]
\[ = \sum_{a=1}^r (b_a - 1) + (e - 4). \]

The formula and also the distribution of the degrees remain valid for \( b = 3; \) only the proof has to be modified, since in this case there is only one generator for \( S^m \) in degree \( 2m \) and therefore no relation for elements in this degree.

Without proof we now list for all exceptional cases the graphs of the corresponding singularities and the number and the degrees of all the basis elements of \( T^l \xi \). Here vertices without weights stand for \((-2)\)-curves, \( b \) is always \( \geq 2 \). It should be mentioned that due to the algorithm described by the second author in [5] it is only necessary to compute \( T^l \xi \) for the cases \( b = 2, 3 \) and 4 in each individual series.

\[
\begin{array}{c|c|c}
\xi & \text{dim}(T^l \xi) & b \geq 2 \\
\hline
2m & 2b - 4 & \\
4m & 3 & \\
6m & 2 & \\
\Sigma & 2b + 1 & \\
\end{array}
\]

\[
\begin{array}{c|c}

\]
8. A generalization to quasi-homogeneous surface singularities

In this last section we want to show that our “splitting” method can be generalized to an effective method for computing the vector space \((T^1_X)^*\) for a much wider class of examples than the class of quotient surface singularities. Let for the rest of this manuscript \((X, x)\) denote a quasi-homogeneous normal surface singularity and let \(d_E\) be the Euler derivation which associates to any homogeneous \(f \in \mathcal{O}_{X, x}\) the element \((\deg f) \cdot f \in \mathcal{O}_{X, x}\). Denote by \(I\) the \(\mathcal{O}_{X, x}\)-homomorphism \(\Omega^1_{X, x} \rightarrow \mathcal{O}_{X, x}\), making the diagram

\[
\begin{array}{ccc}
\Omega^1_{X, x} & \xrightarrow{\alpha} & \mathcal{O}_{X, x} \\
\downarrow d & & \downarrow I \\
\mathcal{O}_{X, x} & \xrightarrow{d_E} & \mathcal{O}_{X, x}
\end{array}
\]

commutative. Defining \(E : \Omega^2_{X, x} \rightarrow \Omega^1_{X, x}\) by \(E(\alpha \wedge \beta) := I(\alpha) \cdot \beta - I(\beta) \cdot \alpha\) for \(\alpha, \beta \in \Omega^1_{X, x}\) and extending everything to the (affine) neighbourhood \(X\) we get an exact sequence of \(\mathcal{O}_X\)-sheaves over \(X' = X - \{x\}\):

\[
0 \rightarrow \Omega^2_{X'} \xrightarrow{E} \Omega^1_{X'} \xrightarrow{I} \mathcal{O}_{X'} \rightarrow 0.
\]

Alternatively, view \(d_E\) outside \(x\) as a vector field and define \(I\) and \(E\) by interior multiplication with \(d_E\). The exterior differentiation \(d\) gives a splitting of the associated (graded) sequence of sections, except in degree 0, where we have a cokernel of length 1 on the right. If we tensor this complex with the dualizing sheaf \(\omega_{X'}\), we still have an exact sequence

\[
0 \rightarrow \Omega^2_{X'} \otimes \omega_{X'} \xrightarrow{E\otimes \text{id}} \Omega^1_{X'} \otimes \omega_{X'} \xrightarrow{I\otimes \text{id}} \mathcal{O}_{X'} \otimes \omega_{X'} \rightarrow 0;
\]

but in order to get a split-exact sequence of sections we have to assume a little more. Suppose that

(a) there exists a holomorphic connection \(\nabla : \omega_{X'} \rightarrow \Omega^1_{X'} \otimes \omega_{X'}\) which gives a splitting of \(I \otimes 1 : (I \otimes 1)(\nabla \omega) = (\deg \omega) \cdot \omega\) for any homogeneous section \(\omega \in H^0(X', \omega_{X'}) = H^0(X, \omega_{X})\);

(b) the module \(H^0(X, \omega_{X})\) has no elements in degree 0.

Then, it is well known (and easy to check) that the \(C\)-linear map

\[
\Delta : \Omega^1_{X'} \otimes \omega_{X'} \rightarrow \Omega^2_{X'} \otimes \omega_{X'}
\]

with \(\Delta(\eta \otimes \omega) := \eta \otimes \omega - \eta \wedge \nabla \omega\) is well defined, and that the pair \((\nabla, \Delta)\) gives a splitting of the sections of (44). For example, we show that — on the \(p\)-th graded piece of \(H^0(X', \Omega^1_{X'} \otimes \omega_{X'})\) — the Lie derivative with respect to \(\nabla\), which is defined by

\[
L_{\nabla} = \nabla \circ (I \otimes \text{id}) + (E \otimes \text{id}) \circ \Delta,
\]
acts by multiplication with \( p_i \). Let \( \eta \) be a 1-form of degree \( k \) and \( \omega \) a 2-form of degree \( l \) and let \( V\omega = \sum \xi_i \otimes \omega_i \). Then

\[
L_p (\eta \otimes \omega) = dI (\eta) \otimes \omega + E (d\eta) \otimes \omega + I (\eta) \cdot V\omega - (E \otimes \text{id}) (\eta \wedge V\omega) \\
= k \cdot \eta \otimes \omega + I (\eta) \cdot \sum \xi_i \otimes \omega_i - (E \otimes \text{id}) (\sum \eta \wedge \xi_i \otimes \omega_i) \\
= k \cdot \eta \otimes \omega + \eta \otimes (I \otimes \text{id}) (V\omega) \\
= (k + l) \eta \otimes \omega.
\]

Now we have an exact vertical sequence in the following diagram:

The mappings \( \mu, K \) and \( J \) are given by

\[
\mu (\omega_1, \ldots, \omega_e) = \sum_{e=1}^e df_e \otimes \omega_e, \\
K (\omega_1, \ldots, \omega_e) = \sum_{e=1}^e l_e f_e \omega_e, \quad l_e = \deg f_e, \\
J (\omega_1, \ldots, \omega_e) = - \sum_{e=1}^e df_e \wedge \omega_e,
\]

and the relations \( K = (I \otimes \text{id}) \circ \mu, J = \Delta \circ \mu \) hold. Again, \( \{f_1, \ldots, f_e\} \) denotes a set of homogeneous generators of the maximal ideal \( m_{X, \omega} \). So, we get an exact sequence

\[
0 \rightarrow \text{im} (J | \ker K) \rightarrow (T^1_X)^* \rightarrow (\omega_{X, \omega}/m_{X, \omega} \omega_{X, \omega}) \rightarrow 0
\]

(1) As J. Wahl informed us the idea to prove exactness by means of Lie derivatives was already used by I. Naruki, *A note on isolated singularity II*, Proc. Japan Acad. 51 (1975), 380–383.
as in Theorem 3, such that the dualizing module $\omega_{X,x}$ contributes $d$ independent infinitesimal deformations, if $d$ is the cardinality of a minimal set of generators of $\omega_{X,x}$.

Remark. J. Wahl has shown ([15]) that the dual of the natural map on the right of (46) has a kernel of length one if $X$ is Gorenstein and that it is injective otherwise. Thus, to get exactness of the sequence (46), we might replace (b) by the assumption that $X$ is not Gorenstein. It is not known to us whether the connection in (a) always exists.

Example. Let $(Y, y)$ denote a quasi-homogeneous Gorenstein surface singularity, and let $H$ be a finite group acting on $(Y, y)$ such that

(i) $H$ acts freely on \( Y' = Y - \{ y \} \);

(ii) the action is compatible with the $\mathbb{C}^*$-action on $Y$.

Then the quotient \( X = Y/H \) is a normal quasi-homogeneous surface singularity. The restriction of the Euler derivation \( d_{\mathcal{E}} \) of $\mathcal{O}_{Y,y}$ to the invariant subring \( \mathcal{O}_{Y,y}^H \cong \mathcal{O}_{X,x} \) is the Euler derivation of the graded algebra \( \mathcal{O}_{X,x} \). Also, \( \Omega^1_X = (\pi_* \Omega^1_Y)^H \), where $\pi : Y \to X$ is the canonical quotient map. This implies immediately that the maps $I$ and $E$ on $Y$ induce the corresponding maps $I$ and $E$ on $X$. Let, moreover, $\chi$ be the character attached to the action of $H$ on $\omega_{Y,y}$. Then (44) is canonically isomorphic to the sequence

$$
0 \to (\pi_* \Omega^1_Y)^H \to \mathcal{O}_{Y,y} \to \mathcal{O}_{X,x} \to 0.
$$

If we assume, moreover, that

(iii) the character $\chi$ is not trivial,

then the remarks above apply. The connection $V : \omega_{X,x} \to \Omega^1_X \otimes \omega_{X,x}$ is given by restricting the exterior differentiation on $Y$ to the eigenspace

$$
(\mathcal{O}_{Y,y}^H \cong \omega_{X,x}.
$$

As an application we can take any quasi-homogeneous rational surface singularity $(X, x)$ of embedding dimension $e \geq 4$ and $Y$ the canonical Gorenstein cover of $X$ (see [13]). Then (a), (b) and (c) hold; in particular \( \dim T^1_X \geq e - 2 \).

Remark. In [14] J. Wahl proved that a good $\mathbb{C}^*$-action in the center of the maximal reductive group of automorphisms exists. For this action, the assumption (ii) is automatically satisfied.

We apply the preceding considerations to the quasi-homogeneous rational singularity $(X, x)$ of embedding dimension $e = 6$ with dual graph

```
  -3
  -3-3
```

whose canonical Gorenstein cover $Y$ is the simple elliptic singularity $\tilde{E}_6$ given by

$$z^3 = x^3 + y^3$$

in $\mathbb{C}^3$. The projection $\pi: Y \to X$ is induced by the $\mathbb{Z}_3$-action $\zeta \cdot (x, y, z) = (\zeta x, \zeta^2 y, \zeta z)$, $\zeta$ a third root of unity (see [13]). In fact, the invariant algebra

$$\mathcal{O}_{X,x} \cong \mathcal{O}_{Y,y}^H, \quad H = \mathbb{Z}_3,$$

is generated by the 6 elements

$$f_1 = xy, \quad f_2 = yz, \quad f_3 = x^3, \quad f_4 = y^3, \quad f_5 = x^2 z, \quad f_6 = x z^2.$$ 

The dualizing sheaf of $Y$ is free with basis element

$$\frac{dx \wedge dy}{z^2} = -\frac{dy \wedge dz}{x^2} = \frac{dx \wedge dz}{y^2}$$

such that $\zeta$ acts by multiplication, and the corresponding character $\chi$ is multiplication by $\zeta^2$. Hence, a minimal set of generators for

$$\omega_{X,x} \cong (\mathcal{O}_{Y,y})^H_X$$

consists of the $e - 2 = 4$ elements

$$\tilde{\omega}_1 = y, \quad \tilde{\omega}_2 = x^2, \quad \tilde{\omega}_3 = x z, \quad \tilde{\omega}_4 = z^2.$$ 

In the following table we list the elements of $(\mathcal{O}_{Y,y})^H_X$ of low degrees, the elements in boxes being the generators over $\mathcal{O}_{X,x} \cong (\mathcal{O}_{Y,y})^H$:

<table>
<thead>
<tr>
<th>x</th>
<th>z</th>
</tr>
</thead>
<tbody>
<tr>
<td>y^2</td>
<td></td>
</tr>
<tr>
<td>x^2 y</td>
<td>x y z</td>
</tr>
<tr>
<td>x^3</td>
<td>x^2 z</td>
</tr>
<tr>
<td>x^3 y^2</td>
<td>x^2 y^2 z</td>
</tr>
</tbody>
</table>

Obviously there are no elements of $\ker K$ in degree 1, 2 and 3. In degree 4 there are 6 linearly independent relations:

1. $(3f_3) \cdot 2\tilde{\omega}_1 - (2f_1) \cdot 3\tilde{\omega}_2 = 0,$
2. $(3f_3) \cdot 2\tilde{\omega}_1 - (2f_1) \cdot 3\tilde{\omega}_3 = 0,$
3. \((3f_3)\cdot 2\tilde{\omega}_1 - (2f_2)\cdot 3\tilde{\omega}_2 = 0\),
4. \((3f_4)\cdot 2\tilde{\omega}_1 - (2f_3)\cdot 3\tilde{\omega}_4 = 0\),
5. \((3f_6)\cdot 2\tilde{\omega}_1 - (2f_2)\cdot 3\tilde{\omega}_3 = 0\),
6. \((3f_3)\cdot 2\tilde{\omega}_1 + (3f_4)\cdot 2\tilde{\omega}_1 - (2f_2)\cdot 3\tilde{\omega}_4 = 0\).

We compute the values of \(J\) for these relations:
1. \(df_3 \wedge 2\mathcal{V}\tilde{\omega}_1 - df_1 \wedge 3\mathcal{V}\tilde{\omega}_2 = 3x^2 dx \wedge (2dy) - (ydx + xdy) \wedge (3 \cdot 2xdx)\)
   \[= 12x^2 z^2 \cdot \frac{dx \wedge dy}{z^2}.\]
2. \(df_3 \wedge 2\mathcal{V}\tilde{\omega}_1 - df_1 \wedge 3\mathcal{V}\tilde{\omega}_3 = (2xz dx + x^2 dz) \wedge 2dy\)
   \[-(ydx + xdy) \wedge 3(zdx + xdz)\]
   \[= (7xz^3 + 5x^4 - 3xy^3) \frac{dx \wedge dy}{z^2}\]
   \[= (12x^4 + 4xy^3) \frac{dx \wedge dy}{z^2}.\]

Similarly
3. \(df_4 \wedge 2\mathcal{V}\tilde{\omega}_1 - df_2 \wedge 3\mathcal{V}\tilde{\omega}_2 = (12x^4 + 16xy^3) \frac{dx \wedge dy}{z^2},\)
4. \(df_6 \wedge 2\mathcal{V}\tilde{\omega}_1 - df_3 \wedge 3\mathcal{V}\tilde{\omega}_4 = (12x^3 z - 4y^3 z) \frac{dx \wedge dy}{z^2},\)
5. \(df_6 \wedge 2\mathcal{V}\tilde{\omega}_1 - df_2 \wedge 3\mathcal{V}\tilde{\omega}_3 = (12x^3 z + 8y^3 z) \frac{dx \wedge dy}{z^2},\)
6. \(df_3 \wedge 2\mathcal{V}\tilde{\omega}_1 + df_4 \wedge 2\mathcal{V}\tilde{\omega}_1 - df_2 \wedge 3\mathcal{V}\tilde{\omega}_4 = 12x^2 z^2 \frac{dx \wedge dy}{z^2}.\)

These elements span the degree \(-4\) part of \((\omega_{y,y})_H^4\), so that there is no nontrivial infinitesimal deformation of degree \(-4\). Together with the \(e - 2 = 4\) deformations coming from \(\omega_{x,x}\) we have
\[1 + 2 = 3\] deformations in degree \(-1\),
\[3 + 1 = 4\] deformations in degree \(-2\),
\[0 + 3 = 3\] deformations in degree \(-3\),
and no deformation of degree \(-4\).

So we get 10 independent deformations, one more than the number
\[ (e - 4) + \sum_{e=1}^{r} (b_e - 1) \]
would suggest. Of course, this was known long time ago by J. Wahl (see e.g. [2]).

We claim that in fact \(\dim T^1_x = 10\). To prove the claim, observe that
homogeneous generators of the local ring are in degrees 2 and 3, and
equations, having quadratic initial forms, are in degrees 5 and 6. Since a
minimal set of generating relations consists of linear relations, all entries of a
homogeneous first order lifting of the matrix of relations must be
homogeneous of degree 2 or 3. But from the minimality one concludes
immediately that all deformations of negative degree at least 5 actually have
to show up in any first order lifting of the relations.
